CRREL Scientific and Technical Reports

Effective scientific and technical research depends on the transfer of information throughout the scientific community as well as the general dissemination of information to the public. CRREL has maintained an active publication program since its inception. This publications list is the supplement to the CRREL Publications List dated December 1975. The following descriptions are meant to clarify the CRREL report series.

CRREL Reports The results of all major research efforts at CRREL are published in the CRREL Report series.

Special Reports

The Special Report series contains a wide variety of reports that do not fall within the CRREL Report category, e.g. literature reviews, data compilations, interim reports.

Monographs

The Cold Regions Science and Engineering Monograph series comprises comprehensive reviews of a field of scientific or technical knowledge with analysis and evaluation. This series is not published on a regular basis and the numbers and frequency vary from year to year. This series would be considered classics in the field of cold regions science and engineering.

Miscellaneous Publications This series includes papers by CRREL authors that are published outside the laboratory but under CRREL funding. This series would include conference proceedings, contract reports, and journal articles.

Internal Reports and Technical Notes This series is not listed in our publications list but frequently is referred to in literature cited by CRREL authors. These documents have not been published for reasons such as proprietary information, excessive expense, limited interest, or awkwardness of format. Copies are available for review in the CRREL Library or with the author's explicit release. Technical Notes are informal, preliminary, unedited, and frequently superceded by a more formal CRREL publication. These are also not available for external distribution without prior permission from the author.

Stibliography on Cold Regions Science and Technology The Bibliography on Cold Regions Science and Technology has been sponsored at the Library of Congress by CRREL since 1951. This most important CRREL product has been published in volumes 1–15 as the Bibliography on Snow, Ice and Permafrost, SIPRE Report 12. Beginning with volume 16 the title was changed to Bibliography on

Snow, Ice, and Frozen Ground, with Abstracts, and with volume 23 the current title was adopted. This publication differs from the CRREL Publications List because it includes all the world's cold regions research in addition to the CRREL in-house work.

Almost all the literature cited in the Bibliographyon Cold Regions Science and Technology has been microfiched and is available in full text from the Library of Congress. If your requests number fewer than 10 you may borrow documents from the CRREL Library, 72 Lyme Road, Hanover, New Hampshire 03755-1290. Those interested in purchasing a photocopy of a document cited should write to the Library.

The *Bibliography* is available for purchase in three formats:

- Online searching is offered as FILE COLD through Orbit Search Service, 8000 Westpark Drive, MacLean, Virginia 22102 (phone 703-442-0900 or 800-445-7248).
- A CD-ROM version, Arctic and Antarctic Regions, is available from NISC, Suite 6, Wyman Towers, 3100 St. Paul St., Baltimore, Maryland 21218 (phone 301-243-0797 or FAX 301-243-0982).
- The paper version currently in 44 volumes is available for purchase from the National Technical Information Service (NTIS), Springfield, Virginia 22161 (phone 703-487-4650). The annual volume appears in two parts: author/subject index and the numerical listing. Every five years a five-year author/subject index has been published to simplify the search process.

Current Literature is a monthly listing of items added the previous month to the Bibliography on Cold Regions Science and Technology. This list is produced by the Library of Congress monthly. The monthly Current Literature comprises the annual volume of the Bibliography on Cold Regions Science and Technology. Only the annual volumes contain indexes. To receive the Current Literature, write to U.S. Army CRREL, Technical Communications Branch, 72 Lyme Road, Hanover, New Hampshire 03755-1290.

The CRREL Reports, Special Reports and Monographs are all available for purchase from the National Technical Information Service (NTIS), Springfield, Virginia 22161. The telephone number is 703-487-4650. Please refer to the next page for ordering information, or copy the form.

CRREL REPORTS

CR 76-01 ARCTIC ENVIRONMENT AND THE ARCTIC SURFACE EFFECT VEHICLE.

Sterrett, K.F., Jan. 1976, 28p., ADA-024 849, Bibliog.

raphy p.25-28.
31-4161
AIR CUSHION VEHICLES, SEA ICE, GRAPHIC FEATURES, ARCTIC LANDSCAPES. GRAPHIC FEATURES, ARCTIC LANDSCAPES. This report summarizes the advances in understanding of the Arctic which have come about since the inception of the ARPA Arctic Surface Effect Velucie Program in 1970, primarily as the result of CRREL's participation. Major efforts to increase knowledge of sea ice, terrestrial, and coastal topographic features are described. Special emphasis is placed upon the quantitative understanding of pressure ridging. Other areas of major interest are atmospheric cheracteristics and ecological effects. A list of publications generated is included.

CR 76-02 PROTECTED MEMBRANE ROOFS IN COLD

REGIONS. Aamot, H.W.C., et al, Mar. 1976, 27p., ADA-025 226, 32 refs

31-4167

WATERPROOFING, INSULATION. ROOFS. COST ANALYSIS.

COST ANALYSIS.
Protected membrane roofs have the prerequisites for better performance and the experience to date is encouraging. The results of performance measurements of three roofs built by the Corps of Engineers verify that the mambrane remains at nearly constant temperature, independent of the weather, and that the insulation retains its integrity despite periodic wetting. Moisture absorption is slow and appears to stabilize in time due to the self-drying nature of the roof. Heat losses are increased due to rain, and extra insulation should be added to compensate for these losses. The resistance of protected membrane roofs to fire, traffic, impact, and other adverse forces is superior. So far, the initial cost of protected membrane roofs is at a premium, primarily due to the cost of concrete pavers. The initial cost premium can be justified, however, by the reduced repair and maintenance costs as indicated to date, and by the longer life expectancy of the protected membrane. The high probability of superior performance and cost effectiveness is a compelling reason to incorporate protected membrane roofs increasingly in Government construction.

CR 76-03 CR 76-63 SURVEY OF DESIGN CRITERIA FOR HAR-BORS AND CHANNELS IN COLD REGIONS— AN ANNOTATED BIBLIOGRAPHY. Haynes, F.D., Mar. 1976, 32p., ADA-025 226.

31-4163 BIBLIOGRAPHIES, PORTS, CHANNELS (WA-TERWAYS), ICE LOADS, DESIGN CRITERIA

A world-wide review of the literature applicable to the design of harbors and channels in cold regions was conducted Forces due to ice movement present the domicant factor in the design of marine structures in cold regions. Expressions for calculating the ice force are presented. Other factors relating to design criteria such as construction materials, structure geometry, and methods of ice suppression are discussed.

ISLANDS OF GROUNDED SEA ICE Kovacs, A., et al, Apr. 1976, 24p., ADA-025 257, 26

Gow, A.J., Dehn, W.F.

31-4164 SEA ICE, ICE ISLANDS, SPACEBORNE PHO-TOGRAPHY.

TOGRAPHY.

Large areas of grounded sea ice have been reported by early arctic explorers and more recently by the U.S. Coast Guard. The ESSA, ERTS, NOAA and DMSP satellites now provide multispectral imagery with sufficiently high resolution to allow detailed sequential observations to be made of the monement and spatial extent of arctic sea ice. This report discusses the location, formation and decay of five large (>30 sq km) islands of grounded sea ice in the southern Chukchi Sea as observed for an extended period of time using satellite imagery. Measurements of the bathymetry around one grounded sea ice feature are presented along with observations made and photos taken from the cosurface. The potential use of these sea ice islands as research stations. be potential use of these sea are islands as research stations also discussed.

CR 76-05 INTERPRETATION OF THE TENSILE STRENGTH OF ICE UNDER TRIAXIAL INTERPRETATION TENSILE Nevel, D.E., et al, Apr. 1976, 9p., ADA-027 042, 12

refe

Hayn s, F.D.

31-4165 ICE STRENGTH, TENSILE STRENGTH, THEO-RIES, STRESSES.

RIES, STRESSES.

Griffith, and later Babel, have previously developed a tensile fracture criterion for a two-dimensional state of stress. This theory is extended to the compression-compression region. From this theory the angle of fracture is developed. The tentory is extended conceptually to three dimensions. al test data by Haynes for snow-ice are shown in this three-dimensional fracture theory. The test data are slightly less than those predicted when the void in the snow-ice is spherical.

CR 76-96 WATER PLOW THROUGH VEINS IN ICE. ADA-026 631, 8 eck, S.C., Apr. 1976, 5p., ADA-026 631. 8 refs. 31-4166

GLACIERS, WATER FLOW, WATER PRESSURE, POROUS MATERIALS.

Water flow through the vein structure of temperate ice is described as Durcian flow in which the pressure gradient is determined from vein size and overburden pressure. A solution method for the resulting equation is given and two special cases are considered.

For steady flow the equilibrate. vein size is a function of depth and, by neglecting the effects of diffusion, it is shown that flow perturbations introduced at the surface propagate downward at a constant speed. These perturbations propagate so slowly that even annual surface fluctuations of fluw may be channated by diffusion before reaching the bottom of the glacier.

CR 76-07
CANTILEVER BEAM TESTS ON REINFORCED

Ohstrom, E.G., et al. Apr. 1976, 12p., ADA-025 380, 6 refs

DenHartog, S.L.

31-4167

ICE STRENGTH, ICE ROADS, FLOATING ICE, REINFORCEMENT (STRUCTURES).

REINFORCEMENT (STRUCTURES).

To determine the effectiveness of reinforcement in ice roads or other uses of a floating ice sheet a series of in-situ cantilever beam tests were run in both seawater ice and frenhwater ice. Tests were run using 1-in-diameter tree branches, 3/16-in-diameter wire rope and 9/16-in, half-round wood dowels. The tests demonstrated clearly that properly placed reinforcement increases the bending strength of the ice and showed further that reinforcement reduces the chance of equipment loss. The question of whether to reinforce or simply grow a thicker ice sheet has not been addressed as this is more a problem of local economics.

TENTS IN FROZEN SOILS FROM LIQUID DETERMINATIONS. PREDICTION OF UNFROZEN WATER CON-

Tice, A.R., et al, Apr. 1976, 9p., ADA-026 632, 30 refe

Anderson, D.M., Banin, A.

31-4168

SOIL WATER, UNFROZEN WATER CONTENT. SOIL WATER, UNFROZEN WATER CONTENT. During the past decade a number of methods for measuring the amount of unfrozen water in partially frozen ground have emerged.

Means of quickly and simply predicting unfrozen water contents in elay have become increasingly important with the growth of interest in encapsulating elay soils compacted at low water contents to serve as baccourses for roads. Unfortunately the measurements require sophisticated equipment and, in most instances, specially trained operators. In an effort to simplify the task of obtaining water-ice phase composition data, methods of calulating observements on curves from other, sumbler measurements. obtaining water-ice phase composition tast, memorals or car-culating phase composition curves from other, simpler measure-ments on soils have been sought. In this paper we present a method of deriving the measurement of unfrozen water contents at various temperatures from liquid l-mit determina-tions. Previous studies have indicated that phase composi-tion curves can be well represented by a simple power equation, W sub u = alpha x theta sup beta, where W sub u is the unfrozen water content in g HZ/0g soil, theta is the temperature in degrees below freezing and alpha and beta are empirical constants characteristic of a given soil. When the liquid limits of a large group of soils encompassing a wide range of textures were regressed against values of alpha, the correlation was found to be remarkably good. This has permitted the development of a recustion equation of sufficient accuracy for general engineering use. sition curves from other, simpler measure-

CR 75.00 SITE ACCESS FOR A SUBARCTIC RESEARCH EFFORT.

Slaughter, C.W., Apr. 1976, 13p., ADA-026 624, 9

31-4169

RESEARCH PROJECTS, REMOTE SENSING. SITE ACCESSIBILITY.

Access to study areas may be an important factor in low term field-oriented research, particularly in regions with well-developed road and communications systems. In term field-oriented research, particularly in regions without well-developed road and communications systems. In a wildhand hydrometeorology research project in subarctic Alaska, access to and within a 40-square-mile research watershed has been developed both in accordance with a general plan prepared at project inception and in response to developing research requirements. Foot trails, trails for "off-read" low-ground-pressure tracked vehicles, belicopper transport, long-term data recorders, and radio telemetry of data have all been incorporated in an access and communications system. Cost estimates indicate that incorporation of gravit roads into the system would be economically advantageous, given adequate funding for initial road construction.

CR 76-10 DE-ICING USING LASERS.

Lane, J.W., et al, Apr. 1976, 25p., ADA-026 637. 27 eole

Marshall, S.J.

31-4170

ICE REMOVAL, LASERS, STRUCTURES, DAM-AGE.

AGE. The feasibility of employing a laser to de-ice remote surfaces was investigated. A Nd-Glass laser, wavelength 1.06 micrometers, and a Ruby laser, wavelength 6943Å, were used to irraducte ice grown upon six types of substrates—suphalt, brass, converte, alumnamm, steel, and stame. It was found that a single pulse, delivered to the interface between the ice and its substrate at a power density of 100 malion to 1 billion watts/ent2, produced fractures 0.1 to 2 cm in diameter for all substrates. If the initial fracture could be propagated by suitables examing of the optical beam over the interface, the ice could be disrupted and thus removed from the substrate. The stechnique could also be a useful adjunct to de-icing method that depend upon the enistence of an initial crack. The process of producing the initial fracture was found to be limited by that hickness of the ice, the bubble content of the ice, and the focusing system. focusing system

CR 76-11 CR 70-11 EFFECTS OF RADIATION PENETRATION ON SNOWMELT RUNOFF HYDROGRAPHS. Colbeck, S.C., Apr. 1976, 9p., ADA-025 763, 10 mfs. For this report from snowher source see 31-4211.

31-4171

SNOW HYDROLOGY, RUNCFF, RADIATION ARSORPTION

ABSORPTION. Water flow through the unsaturated portion of a surespeck is calculated using various assumptions about the interestion into the snew. The results show that for the purposes of hydrologic forecasting, it is sufficiently accurate to assume that all of the radiation absorption occurs at the surface. The error in the calculation of flow is largest for very shellow snowspecks, but this error is reduced by radiation absorption at the base of the snew and by the resting of richtwater through the saturated based inyer.

CR 76-12 TRANSPER CHARACTERISTICS MELTING AND REFREEZING A DRILL HOLE THROUGH AN ICE SHELF IN A TARCTICA. Yen, Y.-C., et al, Apr. 1976, 15p. ADA-026 365, 3

refs.

HEATTRANSFER, BOREHOLES, ICE SHELVES, ICE MELTING, REGELATION.

ICE MELLTING, REGILLATION.

The heat transfer processes associated with melting and refreeing a drill hale 500 m in depth and (\$150 m in initial
radius through an ice shelf were approximately analyzed.

The results were expressed in graphical from thomag the
time available for experimentation under the incle as a function
of heating duration and heating strength. It was found
that the refluency of she drill hole had a much slower
rate than the angling of the hole. (Auth)

WINTER THERMAL STRUCTURE AND ICE CONDITIONS ON LAKE CHAMPLAIN, VER-MONT.

Bates, R.E., June 1976, 22p., ADA-027 146, 9 refs.

LAKE ICE, THERMAL REGIME. ICE CONDI-TIONS, MEASURING INSTRUMENTS, UNITED STATES-VERMONT-LAKE CHAMPLAIN

The thermal structure and ice conditions of Lake Champlain, a mid-lotitude large lake, near Steburne Point, Verment, were studied during the winter of 1974-75. The lake was instrumented to a depth of 8.5 m with a string of highly calibrated thermisters, connected to a data logger on shore which recorded water temperatures every four lower. An ice mounting system was developed to anchor the thermister string so that ice and water temperatures could be obtained at known levels. This temperature recording system measured vertical and horizontal variations in ice and water temperature regimes during ice formation, growth and decay. Metamardiancial data were measured during the winder seried highly calibrated therm temperature regimes during ice formation, growth and decay. Metacrological data were measured during the winter period November 1974 through March 1975 at the site. Ice stratigraphy was determined for the ice at the site at its maximum sensonal growth for comparison with ice from St. Allans Bay (at the northern end of Lake Champlain) which had formed earlier. Correlations were determined between ice growth and accumulate i ergree days of freezing. The operation of a bother system installed near the measurement site around a service dock was observed.

CR 76-14 THERMAL POLLUTION STUDIES OF PRENCH CREEK, EIELSON AFB, ALASKA. McFadden, T., June 1976, 5p., ADA-027 405, 7 refs.

THERMAL POLLUTION, WATER POLLUTION,

THERMAL POLLUTION, WATER POLLUTION, UNITED STATES—ALASKA—EIELSON AFB. At the height of warm weather in Alaska in 1975, temperature measurements were made to determine the extent of the thermal impact on French Creek due to a condenser cooling water impact from the Eichson AFB Power plant. Water temperature measurements during a two-day period failed to show any significant thermal impact on the water in French Creek. It was concluded that no thermal pollution exists due to this warm water input at the volumes and conditions that presently exist.

CR 76-15 REVEGETATION IN ARCTIC AND SUBARCTIC NORTH AMERICA—A LITERATURE REVIEW. Johnson, L.A., et al. June 1976, 32p., ADA-027 406, Bibliography p.22-28. Van Cleve, K.

31-4175 PLANTS (BOTANY), ARCTIC LANDSCAPES, SUBARCTIC LANDSCAPES, REVEGETATION.

SUBARCHE LANDSCAPES, REVEGETATION.

A literature review of revegetation and biological aspects of restoration research was completed for arctic and subarctic North America. Although there is a great dead of climatic variation in this region it is generally characterized by extreme andictions, such as a short growing season and permitrost. Most of the revegetation research has been undertaken in the last nX years so a result of increased natural resource development. The princing goal has been enosion control, with aesthetics, minimization of thermokarst, and production development. The princip goal has been erosion control, with aesthetics, minimization of thermolarst, and production of broate as other rejectives. Revegetation and long-term restoration methods depend upon such variables as the size conditions, notrent regime (especially as this is influenced by the elimatic conditions in the Arctic and Subarctic), plant adaptations, and the selection of native or introduced spicies. Technologies where have been developed to meet these evolutions primarily include seeding methods. Most of such mines, and ferthization and seeding methods. Most of such mines, and ferthization and seeding methods. Most of such sizes, and regimes. There are selected on the basis of a number of factor, such as cold hardinens and growth form prior to evaluation in the laboratory and the field. The most successful species to dete have been Arctared fescue and Nugget bluegrass in the Arctic, while these two as well as creeping red fescue, sender wheatgrass, and Icelandic on distribution and Subarctic. Similar methods have been attempted to a more limited extent with evaluation of native herbaceus and woody species which seem promising on the basis of uniteral, succession studies. There are a number of continuing research needs for arctic and subsectic respectation. These include fertilization strategies, development of specialized techniques (such as springing) for native species, and longer term studies. It is pericularly important on mingrate short-term revegetation methods with long-term restoration gasks. t CHOTALION BANKS.

MECHANICS OF CUITING AND BORING. PART II: KINEMATICS OF AXIAL ROTATION MACHINES.

ROCK DRILLING, EXCAVATION, CUTTING TOOLS, CONTINUOUS BELT MACHINES.

TOOLS, CONTINUOUS BELT MACHINES. This report, which is one of a series on the mechanics of cutting and boring in rock, deals with the kinematics of mechanes which utilize a continuous belt as the cutting unit (e.g. coal saws, shale saws, diagner-chain trenchers). The discussion and analysis covers the geometry and motion of various components of the cutting system, including such topics as chipping depth, production and conveyance of cutings, tool trajectorics, tool speeds, tool angles, and arrangement of cutting tools on the belt. Worked examples are included to libustrate the application of various equations to practical realisms.

THICKNESS AND ROUGHNESS VARIATIONS
OF ARCTIC MULTIYEAR SEA ICE.

Ackley, S.F., et al, June 1976, 25p., ADA-028 066, 11

Hibler, W.D., III, Kugzruk, F.K., Kovacs, A., Weeks, 31-4170

SEA ICE, ICE COVER THICKNESS, SURFACE ROUGHNESS, MODELS.

Three surface elevation and ice thickness profiles obtained during the 1972 Arctic Ice Dynamics Joint Experiment Pilot Study on a multiprar ice flow were gestlyzed to obtain relationships between the surface elevation, thickness and physical properties of the ice. It was found that for ice freeboards Study on a musicycar ice flow were entity and to obtain relationships between the surface cleviation, thickness and physical properties of the ice. It was found that for ice freeboards from 0.10 m to 1.05 m above sea level a linear relationship between the ice density and the freeboard could be postulated in a statistical relationship consistent with the observed physical properties, which indicate that as the ice freeboard increases, the ice salinity decreases and the higher freeboard or thicker ice therefore decreases in density. Using this variable density with freeboard relationship, a madel was constructed to predict the ice thickness, given the ice freeboard and anow depth alone. The model was compared with two other models, one assuming constant ice density (independent of freeboard) and the other using smoothing fifters for predicting the ice thickness. It was found that the variable density prediction madel gave the best approximation to the observed ice thickness, with a standard error between the measured and predicted value of about 0.6 m, compared with errors from 50 to 1007; higher for the other two models. The model was also compared with dota on multiyear ice from two other investigations in different regions and was found to give error estimates similar to the error of the data set on which the model can be useful to estimate multiyear ice thicknesses from surface elevation information obtained either by ground-based techniques or by aerial methods such as laner profitometry or stereo aerial photogrammetry. The effect of the variable density on estimates of the stress induced in the ice sheet by instante imbalance loading was examined and the results are presented in an appendix. Consideration of this property led to the conclusion that stresses from sources other than isostitic imbalance must account for 75% or more of the bending stresses necessary to induce cracking in multi-year ice.

CR 76-19 WASTEWATER RENOVATION BY A PROTO-TYPE SLOW INFILTRATION LAND TREAT-MENT SYSTEM.

Iskandar, I.K., et al. June 1976, 44p., ADA-029 744, Bibliography p.33-35. Sletten, R.S., Leggett, D.C., Jenkins, T.F.

32-1066

WASTE TREATMENT, WATER TREATMENT, SOIL CHEMISTRY, SEEPAGE.

The feasibility of a slow-infiltration land treatment system as an alternative to advanced waste treatment of wastewater was studied using six outdoor test cells. Wastewater was was studied using six outdoor test cells. Wastewater was applied to forage grasses by spray irrigation. Farameters studied were wastewater application rate, effect of pretreatment and soil type and seasonal effects on the treatment system. Activated sludge pretreatment of the applied wastewater did not improve the overall quality of the product water from this slow-infiltration system. The upsake of nutrients by forage grasses accounted for significant removal of nitrogen and phosphorus from applied wastewater during the growing season. Other renovative mechanisms, namely nitrification of applied nitrogen and phosphorus immobilization and fixation by the soils may have accounted for further renovation of the applied effuents. The introgen loading rate appeared to be the critical factor in limiting loading rate appeared to be the critical factor in limiting securing removation of the applied efflicits. The nitrogen loading rate appeared to be the critical factor in limiting the amount of wastewater that could be successfully applied to this type of land treatment system, at least over the to this type of land treatment system, at least over the short term. Also the renevative mechanisms for nitrogen were found to be seasonally dependent. Due to decreased nitrification and sorption of arimonium by soil components introgen was stored in the winter months. The sorbed ammonium underwent nitrification in the warmer months, giving rise to a high concentrations observed in leachate after the first very of waitenages, and increases after the first very of waitenages. the first year of wastewater application were attributed to mineralization of native organic-5. Application of 15 cm/week of secondary effluent containing 27 mg/l total

N to sandy loant soil produced percolate water containin NO3-N concentrations consistently in excess of accept drinking water standards (10 mg NO3-N/1), Leachin phosphorus was not observed but needs further study predict long-term effects. Winter-time application was successful in terms of operational parameters, but the renovati phosphorus was not observed but needs further study to predict long-term effects. Winter-time application was suc-cessful in terms of operational parameters, but the renovative capacity for nitrogen was impaired. The effect on the other water quality parameters such as suapended solids, BOD, fecal coliform and organic-C was essentially complete removal. There was a negative chloride balance which was presumed to be due to plant uptake.

CR 76-20 APPARENT ANOMALY IN FREEZING OF OR-

DINARY WATER. Swinzow, G.K., June 1976, 23p., ADA-039 177, 9 refs. 32-1067

ICE FORMATION, ICE CRYSTAL NUCLEI, SUPERCOOLED WATER, IMPURITIES, TEMPERATURE VARIATIONS, LABORATORY TECHNIQUES.

TECHNIQUES. Under orditions the freezing of water begins with supercooling and ice nucleation, and proceeds at OC at the ice/water interface until ice formation stops. The presence of solutes, high pressure, or dispersal in fine pores causes the water to freeze at temperatures below OC (the so-called freezing point depression). Whenever freezing begins, it proceeds at a constant temperature, or at a temperature which becomes propressively lower. A temperature rise during ice formation is considered here to be an aboundly. Under all cound circumstances, the conditions under which during ice formation is considered here to be an anomaly. Under all equal circumstances, the conditions under which an anomalous freezing temperature is observable appear to be very special. This repriv describes two deflerent experiments displaying the anomalous rise of temperature after nucleation and during ice formation. In one case twater was dispersed in the fine pures of fine powders; in the other case pure water was frozen in a transparent insoluted cell. Photographic observations were made; relations of ice surface to water volume were measured.

CR 76-21 COMPRESSIBILITY CHARACTERISTICS OF COMPACTED SNOW.

Abele, G., et al, June 1976, 47p., ADA-028 622, 5 refs. Gow. A.J.

32-1068 SNOW TEMPERATURE, SNOW DENSITY, SNOW DEFORMATION, STRESSES, PHASE TRANSFORMATIONS, RECRYSTALLIZATION. TRANSPORMATIONS, RECRYSTALLIZATION, The effects of snow temperature and initial density on the stress vs density and stress vs deformation relativiships were investigated for shallow compacted snow in the density range of 0.28 to 0.76 g/cu cm. for a stress range of 0.5 to 72 bars and a temperature range of -1 to -34C at a deformation rate of 40 cm/sec. A decrease in temperature increases the resistance to stress, the effect increasing with applied stress. For any stress, an increase in the initial density results in an increase in the resulting density, the effect decreasing with an increase in stress. The approximate decreasing with an increase in stress. The approximate specific envelopes, which define the stress required to inition any deformation of snow of a particular density and temperature, were determined. Rapid compaction of snow result in extensive recrystallization, significantly different from the of naturally compacted snow. At a stress of 72 bon transformation to see occurs only at temperatures above.

CR 76-22 EVALUATION OF MESL MEMBRANE—PUNC-TURE, STIFFNESS, TEMPERATURE, SOL-VENTS

Sayward, J.M., June 1976, 60p., ADA-027 834, 30 32-1069

SOIL STRUCTURE, SOIL STRENGTH, PROTEC-TIVE COATINGS, FROST PROTECTION, CEL-LULAR PLASTICS.

Several membrane materials used or considered for MESL (membrane-enveloped seal layer) utilization of poor seals in road construction have been tested for cold effect on puncture and stiffness. PE (polyethylene) film was also tested for solvent soak effects. A symple blunt needle apparatus and stiffness. PE (polyethylene) film was also tested for solvent seak effects. A simple built needle apparatus was devised for puncture testing. For plastic films (mainly PE), both puncture resistance and stiffness increase at low temperature. For non-winen, spunhonded fabrics these properties are little affected by cold. For both non-winens and PE film, puncture and bending strengths increase linearly with weight not hickness. The soope is steeper for the non-winens, which generalls are stronger on a per unit weight hasts. PE film soaked in a hydrecarbon solvent swelled approximately 17% and lost about 30-40% of its puncture strength. These effects are apparently reversible upon drying. Consideration has been given to seasing puncture strength. These effects are apparently reversible upon drying. Consideration has been given to sealing and patching requirements and in the drying of scalant liquids when adhering film to film. Also considered have been possible slippage related to the reported low angle of friction of plastic films in soil and the possibility of lamination for improved. membrane properties.

STUDY OF PILES INSTALLED IN POLAR SNOW.

Kovacs, A., July 1926, 132p., ADA-029 191, 18 refs. 32-1070 PILE DRIVING, SNOW BEARING STRENGTH,

SNOW MECHANICS, GREENLAND.

This report describes the study of piles tested in polar snow at Camp Centery, Greenland. More than 20 piles of various lengths and since were driven, including timber, closed-ond and open-end steel pipe piles, and I- and H-piles. The H-piles were instrumented with strain pages. In addition to the driven piles, two purely end-bearing piles were installed in angered hotes and five piles were frozen in place using a smort-water slury. Driving records were obtained and are discussed. Analysis of the driving response of various piles revealed that the Hiley Soranula, and pre-smootly other similar pile driving formulas, cannot be used to product the ultimate supporting capacity of piles driven in snow. Factors such as pile inertia, rigidity, size, and tip resistance are discussed in relation to their apparent influence upon pile penetrasion. Pile load test procedures are described and test results are discussed. It was found that closed-end pipe piles are decidedly inferne to open-end pipe piles in their load-carrying capability and their ultimate supporting capacity. Although pile settlement was found to be dependent upon such variobles as pile load, time, pile shape, and stow temperature, precise effects of these variobles were not determined. Nevertheless, the capability of open-end piles to carry quite heavy loads was demonstrated and a nearyzed to reveal the strain distribution within a pile during driving and static loading. Excavations revealed the configuration of the denosfied snow deplaced along the sides and beneath the tips of a number of driven piles. Laspections of this displacement gave inought into the carrying response of each pile type.

Langway, C.C., Jr., Weiss, H.V., Hurley, J.P., Kerr, R., 32-1071

SNOW COMPOSITION, CHEMICAL ANALYSIS. ICE CORES, ICE COMPOSITION, IMPURITIES. GREENLAND.

Chemical englysis of surface snows and deeper ice core samples from Milcent, Greenland, indicates a marine onga-fee Na and Cl and a terrestrial origin for Al, Mn and V. Pre-1900 enrichment factors, based on average crustal V. Pre-1900 enrichment factors, based on average crustal composition, are high for Zn and Hg and appear to be related to their volutility. A comparison of pre-1900 and 1971-1973 concentrations of V and Hg shows no decided increase from industrial production, however, the abundance of Zn (relative to Al) increased three-fold during this time period. The chemical composition of ancient ice is extremely useful in interpreting modern aerosols.

CR 76-25 BASELINE DATA ON THE OCEANOGRAPHY OF COOK INLET, ALASKA. Gatto, L.W., July 1976, 84p., ADA-029 358, Bibliog-raphy p.78-81.

OCEAN CURRENTS. TIDAL CURRENTS. WATER CHEMISTRY, SEDIMENT TRANS-PORT, TURBULENT FLOW.

WATER CHEMISTRY, SEDIMENT TRANS-PORT, TURBULENT FLOW.

The primary objective of this investigation was to comple baseine information pertaining to the ocean circulation, especially the extent and patterns of tolal currents and tolal Yushing, in Caok Inlet, Alaska, utilizing aircraft and satellite imagery with corroborative ground truth data. LANDSAT. I and NOAA-2 and -3 imagery provided repetitive, synoptic views of surface currents, water mass imaginton and sediment distribution during deferent seasons and tides. Color, color infrared and thermal infrared imagery acquired on 22 July 1972 with the NASA NP-3A aircraft were used to analyze currents, mixing potterns and sediment dispersion in selective areas. Temperature, salonity and suspended sediment concentration data and hand-held photography were ntilized as ground truth information in the interpretation of the internal tand satellite imagery. Coriolis effect, semidiumal tides and the Alaska current govern the estuary circulation. Clear, oceanic water enters the inter on the southeast during floud tide, progresses northward along the east shore with minor lateral mixing, and remains a distinct water mass to the lottude of Kasifo-Nisukhk. South of the forelands make tide and a shear zone between the two water masses to the lottude of Kasifo-Nisukhk. South of the forelands are constituted in turbid infect south of Kaşi. Island. Currents adjacent to and north of the forelands as, complicated by tidal action, constituted and configuration and bottom effects. Turbulence is gresteet throughout the water column along the south sheer to and north of the forelands as, complicated by Italia action, constal configuration and bottom effects. Turbulence is greatest throughout the water column along the south shore and stransfication is more pronounced in Karistska and Kachenak Boys, especially when fresh water simoff is high Most of the soliment discharged into the infet is deposited on the extensive itali flats or removed by Italia currents along the west side during ebb flow. Bottom scouring is evident along the cast shore south of Pr. Possession or more one. CR 76-26

DEBRIS OF THE CHENA RIVER.

SNOW HYDROLOGY, SNOWMELT, RUNOFF. MOISTURE TRANSFER, TUNDRA VEGETA-TION, FOREST LAND.

MOISTURE TRANSFER, TUNDRA VEGETA-TION, FOREST LAND.

In Part I a physically based model was used to predict daily snowmelt on 2,000 sq m plots in the Solurcia. The plots had a range of aspects and inclinations in boreal forest and on the tundra. The energy balance, computed for each of the plots, was compensated for differences in radiative and turbulent energy fluese cannet by varied slope geometry and vegetative cover. The turbulent energy flues were also corrected for the effects of the stable stratification of the air over the snow surface. The predictions of the model were computed with daily mel's derived from runoff measured on the snowmelt plots. The results show that the method is a good predictor of daily announts of snowmelt although some uncertainties are introduced by changes in the stara turface during the melt period. In Part II, a physically based model of the movement of water through snowpacks was used to calculate hydrographs generated by distral waves of snowmelt on the tundra and in the boreal forest of subsectic Labrador. The model was tested against measured hydrographs from hillide plots that sampled as range of aspect, gradent, length, vegetative cover, and snow depth and density. The model yielded good results, particularly in the prediction of peak tunoff rates, though their the ranges over which each of the controls is likely to vary, the two most critical factors controlling the hydrograph are the snow depth and the melt rate, which must be predicted precisely for short intervals of time. Permeability of the snowpack is another supportant control, but it can be estimated closely from published values.

CR 76-28 ANALYSIS OF EXPLOSIVELY GENERATED GROUND MOTIONS USING FOURIER TECH-NIQUES.

Blouin, S.E., et al. August 1976, 86p., ADA-030 060, 18 refs.

The focus of this investigation was to assess the The focus of this investigation was to assess the utility of remote sensing techniques in the study of tand unewater quality relationships in an east central Wisconson test area. The following types of artial unaperty were evaluated for this purpose; high altitude (60,000 ft) color, color infrared, multispectral black and white, and thermal; low altitude (fiess than 5,000 ft) color infrared, multispectral black and white, thermal, and passive microwave. A non-imaging hand-held four-band radiometer was evaluated for utility in write, thermal, and passive microwave. A non-imaging hand-held four-band radiometer was evaluated for utility in providing data on suspended sediment concentrations. Land me analysis includes the development of mapping and quantification methods to obtain baseline data for comparison to water quality variables. Suspended sediment loads in streams, determined from water samples, were related to land use differences and soil types in three major watersheds. A multiple correlation coefficient R of 0.55 was obtained for the relationship between the 0.6-07 micron incident and reflected radiation data from the hand-held radiometer and concurrent ground measurements of suspended solids in streams. Applications of the methods and baseline data developed in this investigation include mapping and quantification of laffects of land use changes on stream sedimentation, and remote sensing of suspended sediment content of streams. High altitude color infrared imagery was found to be the most acceptable remote sensing technique for the mapping and measurement of land use types.

CR 76-31 ANALYSIS OF POTENTIAL ICE JAM SITES ON THE CONNECTICUT RIVER AT WINDSOR. VERMONT.

Calkins, D.J., et al, Sep. 1976, 31p., ADA-031 572, 11

Hutton, M.S., Marlar, T.L.

32-1079

RIVER ICE, ICE JAMS, ICE MECHANICS, WATER FLOW.

Sections in the Connecticut River where ice jam potential is high were identified through the use of low-altitude black and white photographs taken during low-flow, ice-free conditions. The hydraulies and mechanics of ice jam initiation were investigated in the river reach where these sections were identified. Certain areas were found in the river were investigated in the river reach where these sections were identified. Certain areas were found in the river that had a logh susceptibility to see elogging, but this high potential decreased with increasing discharge because of the improved surface conveyance of the see through the reach. The stability of see floors was established along the channel. But the floors generally became unstable as the flow increased. This was calculated by using a Fronde number criterion. Grounding locations for see became evident when the critical Fronde number was zero for a given thathers and water depth. No single factor was determined to be responsible for intuining the see gares in the Connections flower at Windson Apparentis there existed a mutitude of interacting conditions, surface constructions, possible high backwater conditions from the Beattlebore Dam a solid oc cover in the backwater of the Brattlebore Dam that prevented see transport from the Windsor area, deep pools followed by shallow depth sections suptream of bridge piers, a greater see thickness accumulation of fragmented fises than would result if a uniform cover could be established in the same reach, and the diurnal finetization of river stage caused by the referse of water at Wilder Dam.

CR 76-32 GROUNDED ICE IN THE FAST ICE ZONE ALONG THE BEAUFORT SEA COAST OF ALAS-

KA. . A., Sep. 1976, 21p., ADA-031-352, 13 refs. 32-1080

SEA ICE, FAST ICE, ICE PHYSICS, PRESSURE RIDGES

Front large grounded multi-year shear ridge formations were found in the grounded see sub-rone of the fast see rone near the Harmson Bay Frudhow Bay area of Alaska. A lident-long cross section of one of these formations was obtained by leveling and some resonancements. These measurements revealed that the maximum ridge height was 12-6 m and that the formation was grounded in 17-18 m of water. The subsists, temperature, being soldium and density of the see were determined on samples obtained by coring. The physical characteristics of the formations as observed in satellite, SLAB, and arral imagers indicate that these formations have not invised between the time of their formation in the fall of 1978 and August of 1976. Evidence of significant aeolian debits discoloring the see is discussed. Four large grounded multi-year shear ridge formations were found in the exampled we substone of the fast see some

ROCK, FROZEN SOIL AND ICE BREAKAGE BY HIGH-PREQUENCY ELECTROMAGNETIC RADIATION. A REVIEW.

Hoekstra, P., Oct. 1976, 17p., ADA-039 178, 17 refs. 32-1098

ROCK EXCAVATION. FROZEN GROUND STRENGTH, EXCAVATION, DIELECTRIC PROPERTIES, ELECTROMAGNETIC PROPER-TIES, MATHEMATICAL MODELS.

TIES. MATHEMATICAL MODELS.
In the past decade, various workers have investigated the use of high-frequency electromagnetic radiation for breaking and excavating rack and fruten ground. This report reviews the high-frequency dielectric properties of these materials, the physics of heating, and the existing literature on these subjects. The high-frequency defective properties of racks and soils, and the absorption of energy by these materials, are manly determined by their inquid water contents. Computer maching was used to calculate absorption energy as a function of distance behind stradiated faces of earth materials. The returning computations showed that most enery in absorbed in the first few continueers of frozen ground and weak soils. However, in hard rocks of low water content, electromagnetic waves preferrate more decepty, and significant amounts. sous. However, in nare rocks or low water content, executing its water penteral more deceptly, and significant amounts of energy are also absorbed tens of centimeters behind the irradiated faces. Test results showed that electromagnetic neck breakage is feasible only for excavations in head rock; test results from the use of electromagnetic radiation for excavating tunnels in weak rocks and frozen ground are necessarios.

AIRBORNE RESISTIVITY AND MAGNETOME-TER SURVEY IN NORTHERN MAINE POR OB-TAINING INFORMATION ON BEDROCK GEOLOGY.

un. P.V., et al. Oct. 1976, 19p., ADA-032 733, 21 refs

Arcone, S.A., Delancy, A.J. 37,1099

MAGNETIC MEASUREMENT, ELECTRICAL RESISTIVITY, GEOPHYSICAL SURVEYS GEOLOGY, UNITED SYATES-MAINE.

GEOLOGY, UNITED STATES—MAINE.
Geophysical studies were conducted during September and
October of 1975 in northern Maine to Incate reck types
sustable for construction purposes for the proposed Dickeylancoln School Dath Project. Simultaneous authorise imaginetometer and VLF electrical resistivity and of total magnetic
intensity above the cartic's luckground magnetic field. During the same time period, ground and multi-clevation surveys
were performed over a special test sector of known geology.
The ground and archorac study in the test sector aided
in interpretation of the data by revealing a strong correlation
between ignosus geology, resistivity, and magnetic intensey.
Luck of a similar correlation between resistivity and magnetic
data in the remainder of the network new suscented an alternom interpretation of the data by revealing a strong correlation between ignosing goology, resistivity, and magnetic internety Lack of a similar correlation between resistivity and magnetic data in the remainder of the survey area suggested an absence of additional areas of ignorm rocks. The multi-elevation survey of the test area indicated that changes in flight altitude, necessatisted by the topographic relief encountered, would not seriously affect the regional resistivity poterns. Although there was no strong evidence of ignorms rocks outside the test sector, soutable rock types may exist within the Dis geologic time (cyclically hedded gray slote and sandstroer) to the central part of the main survey area, where most of the high resistivity contours occur.

WATER ABSORPTION OF INSULATION IN PROTECTED MEMBRANE ROOFING SYS-TEMS

Schaefer, D., Oct. 1976, 15p., ADA-032 089, 12 refs. 32-1100

INSULATION. PROTECTIVE COATINGS WATERPROOFING, ABSORPTION, ROOFS.

Current methods for evaluation of the menture absorption of plantic insulations (ASTM-C-272-55 and ASTM-C-355-64) due to vapor pressure graderate or immersion rely on short time periods to predict long term performance. This proceeding may not provide accurate information on performance processive that me pressure accurate transmission on performance stage in practice invalidation may absorb more moniture than these tests understee. A series of tests was conducted on estruded polystyrene roof moniture that had been on place, exposed to extruorumental moniture and pressure gradients, for a maximum of 36 months. Results indicate that moniture absorption of 15% by solume can be expected on the field. = the Seld

CR 74-39 EFFECTS OF WASTEWATER APPLICATION ON THE GROWTH AND CHEMICAL COMPO-SITION OF FORAGES.

Palatto, A.J., Oct. 1976, \$p., ADA-032 774, 9 refs. 32.1101

WASTES, WATER, SOIL CHEMISTRY, WATER CHEMISTRY, PLANTS (BOTANY), GRASSES.

The contribution of a forage system in the resonation of wasterstee in the processor is wastersteen by a processor sion infiltration land treatment system was studied from June 1974 to June 1975. The forage was grown in six oridors cells, three contaming a Window sandy Joan soil and three a Cariton set leasn. Direct cells received primary and three received secondary assertances of contract and contract of the secondary cells. wastewater at various application rates. Crop suchle, sods and totale analyses, plant removal efficiency and local update of applied uniforms were existed to the rate of materiales applied. Dry matter production, plant leave metal concer-

traines, and plant removal of nitrogen and phosphorus all increased as the rate of applied wastewater increased from 5 to 15 cm/week. Total dry matter production ranged from 9.63 to 12.99 metric tonethe, and sotal uptake of nitrogen and phosphorus ranged from 309 to 455 kg/ha and from 32 to 42 kg/ha, respectively. An increase in wastewater application rates supercased nitrogen and phosphorus removal efficiency by phasts. Forages receiving 5 cmf/mk of wastewater removed 1745 and 85% of the Napplied during the growing season, in contrast to the 44% removed by those treated with 15 cm/mk of wastewater amount of dry matter and removed more N and leas heavy metals than those grown on the Windoes sole. Soil analyzes in apping 1975 showed reductions in soil pH and in the total amounts of exchangeable estions, as compared to analyzes performed in spring 1974. Soils receiving the present application rate of wastewater showed the greatest reduction. Wastewater application during 1974 increased the amount of soluble soil P. Higher amounts of soil-extractable P were also noted at the highest wastewater applications rate. CR 76-40

ICE, IMPURITIES, PHOTOMACROGRAPHS.

Several original methods were developed to photograph tracts in transparent materials such as ice. The artifo-occurring in the surface, bulk, and interface, were gener 0.01 mm to 70 mm in size. Sample preparation, illuminati focusing and other technical problems are discussed in det Several sample photographs are included.

CR 76-41 **GEODETIC POSITIONS OF BOREHOLE SITES** OF THE GREENLAND ICE SHEET PROGRAM. Mock, S.J., Nov. 1976, 7p., ADA-033 840, 9 refs. 32-1103

GEODETIC SURVEYS, BOREHON SHEETS, ICE CREEP, GREENLAND. DOREHOLES, ICE

Eight Gencerver statues were established and suit Eight Gencerver stansons were established and suitably marked along or near the crestines of the Greenhand see sheet during GISF field operations from 1971 to 1975. At one of these stations, DYE-3, repeated Genceiver positions indicate an see velocity of 127 m/yr on an azimuth of approximately 60 deg. Data from the International Greenhand Glociological Expedition (EGIG) surveys show that ice flow in the vicinity of Crete in radiating outward from a dome to the south. Two independent calculations of the state of equilibrium at Crete indicates ice sheet thusing rates of 0.25 to 0.37 m/yr, while direct measurement of elevation change by EGIG indicates an ice sheet theleng rate of of approx 0.06 m/yr. Resolution of these differences most would further grouphystal work and deep delling in the see sheet.

CR 76-42 ARCHING OF MODEL ICE *1.0ES: EFFECT OF MIXTURE VARIATION G.S TWO BLOCK SIZES

Calkins, D.J., et al, Nov. 1976, 11p., ADA-033 \$41, 5

Ashton, G.D.

32-1104

EXPERIMENTAL DATA, FLOATING ICE, ICE DOOMS.

BOOMS.

A study of arching of mixed, square fragmented see flores at an operating in an ice boom is documented, using results from a model study in which two sizes of plantic blocks represented realise. A power function, relaxing the upstream rice concentration to the ratio of a characteristic block dimension to the gap opening, is found adequate to distinguish between arching and nonacching events for block ministers of two component sizes. It is demonstrated that when the respective total areas of the two block components are nearly equal, a ministerium of the sixels which components are nearly equal, a ministerium secretations sixuates in arch action the opening. As the mixture of two series of blocks approaches a similare none-stroll mixture, a highest concentration of tree is increded to instinct the arch. When the ratio of the block dimensions to the gap opening is equal to set less than 6 10 a seebing of the fragmented see is not possible, even when the upstream ice dockarge exceeds the maximum discharge of ice through a gap opening. The distribution of fragmented see areas is an important parameter in establishing the minimum size of opening at which an ice boson will return its arching capitality.

SUPPRESSION OF ICE FOG FROM COOLING PONDS.

McFadden, T., Nov. 1976, 75p., ADA-035 322, Bibliography p.71-75 32-1105

ICE FOG, FOG FORMATION, FOG DISPERSAL FONDS, IC COATINGS ICE COVER EFFECT, PROTECTIVE

fee for generated at the Firthern ABB power plant crotting pond contributes heavily to the total see for problem on the base. Several methods for see for suppressions were studied and from techniques were total experimentally. Fu-periments were also conducted to determine the magnitude perments were and consecred to accremine the majors of the various modes of heat transfer outless the po-imetoclossate. Values of expositive and radiative li-loss during see fog are presented. Lie cover is sh-

to be an effective ice fog suppression technique. Measurelecture films are also shown to be effective and offer some unique advantages, such as ease of application and low overall cost. The heat normally last to evaporation must be disnipated by other means during suppression. With the ice cover technique this is accomplished by melting must be designed by other means during suppression. With the ice cover technique this is accomplished by suching the ice cover. During suppression with monomolecular films, the heat must be dissipated by increasing radiative and convective losses. The rimplicity of application of monomolecular films, along with their lower cost, contine to make this technique attractive; however, the lower pond his tocompac amount of the see cover technic

CR 76-44 THERMODYNAMIC DEFORMATION OF WET SNOW.

ck, S.C., Nov. 1976, 9p., ADA-033 830, 10 refs.

WET SNOW, SNOW DEFORMATION, THER-MODYNAMIC PROPERTIES.

MODIFICATION. FINATION CONTINUES.
The deformation of wet stow is explained in terms of the thermodynamics of the three phases of water. When deformation by particle rearrangement is fully developed, deformation can occur most rapidly by melting at the puricle context. The rate of deformation is highly sensitive to the liquid names context limit immore content, norticle context total. sensitive to the liquid at, particle contact area The race of deformation is highly sensitive to the liquid water content, ionic impurey content, particle content next, and stress level. A model of the hydrostatic deformation of wet news is constructed, and examples of the deformation of wet news are given for a variety of conditions. These steads are in agreement with existing experimental evidence. The model accurately simulates the transient nature of the deformation and the effect of water consent on the quasi-stable density of wet snow subjected to a constant stress.

AIR CUSHION VEHICLE GROUND CONTACT DIRECTIONAL CONTROL DEVICES Abele, G., et al, Dec. 1976, 15p., ADA-034 825, 3 refs.

Listen, R.A. 32-1107

AIR CUSHION VEHICLES, YAW,

AIR CUSHION VEHICLES, YAW,

The moneuvershiley of air cushion vehicles can become a serious operational problem when the vehicle's travel route to testicious operations problem when the vehicle's travel route to testicious operation of aerodynamic methods may be a more desirable approach, there is a practical limit to these methods and the war of ground contact devices requires considerations for providing more pusitive directional control. Wheels deserve special attention, and therefore are analyzed in more dentil because of their obvious application on a variety of lead terrains. Brake rods and harrows are more multiple on water, see and soon. The succer-object ground contact device would counce the least ecological suspect on finglic organic terrains such as tunden. Relative discession stantisty is evoluted in terms of the total pawing momenta-produced by which arrangements (might, dust, tandem), lecture of the vehicle to determine the state of the vehicle to determine the most efficace operational mode with a particular wheel arrangement for any year condition. The analysis limited to retractible devices which act as moments producing brakes or tollers and do not zeroe as either peoplesion or lead ammone mats. Construined contact with hart sections. to refrectable devices which act as moment producing brakes or rollers and do not serve as either propulsion or band support sale. Controlled ground contact with shart rections having special wearing surfaces may provide a sonable control method and would require the least significant change to the basic design of the vehicle or its components. The concept involves the use of an air flow control mechanisms for defining spacific shirt sections, thus causing shart-ground contact at selected areas of the peripheral shart.

DEFENSIVE WORKS OF SUBARCTIC SNOW. Johnson, P.R., Apr. 1977, 23p, ADA-051 769, 11 refs.

SNOW (CONSTRUCTION MATERIAL), SNOW DENSITY, FORTIFICATIONS, MILITARY OPERATION.

ERATION.

Field tests at Fort Wainwright, Alaska, carried out in March-April 1975 showed that the typical subartice snow of interior Alaska can be used effectively to provide protection from both rifle and machine gun fire. The undisturbed snow had an average density of 0 18 g/cu cm, but simple processing, such as shoveling, increased the density to around 0 34 g/cu cm. Further processing increased the density to above 0 40 g/cu cm, but densities much above that value were difficult to obtain with simple hand equipment. Tests of the Mil6 rifle and M60 and M2HB machine guns showed that bullet penetration was inversely related to density—the higher the density the lower the bullet penetration. Design values for the three weapons were determined. A number of types of snow trenches and structures were designed and tested. They were found to provide good protection, in part since bullets showed a strong tendency to ricochet from the snow surface when striking it at a low angle Burlap bags filled with snow to revet structures worked very well. Several types of Russian defensive works of snow were tested but proved unsuitable in the light, weak subarctic snow. The times required for troops to build evertal types of the stream of the part of the part of the troops to build everal types of the proved unsuitable in the light, weak subarctic snow.

MECHANICS OF CUTTING AND BORING. PART 4: DYNAMICS AND ENERGETICS OF PARALLEL MOTION TOOLS.

Mellor, M., Apr. 1977, 85p., ADA-040 760, Bibliography p.80-82. 32-1142

DRILLING, ROCK EXCAVATION, ICE CUT-TING, BOREHOLE INSTRUMENTS, PERMA-FROST, METALS, DESIGN.

FROST, METALS, DESIGN.

The report deals with the cutting of rock and similar materials by parallel motion tools. It examines cutting forces and energy requirements, taking into consideration tool geometry, wear, operating conditions, and material properties. After an introductory discussion of terminology, some general principles are outlined, and relevant theoretical ideas on metal cutting and rock cutting are reviewed. The next section, which is the heart of the report, reviews experimental data on the magnitudes and directions of cutting forces. There is a graphical compilation of data, including some from obscure or unpublished sources. The variables covered include chipping depth, rake angle, relief angle, side rake, base angle, tool width, tool compliance, tool speed, tool wear, tool interactions, and material properties. The second major part of the report treats the energetics of cutting it begins with a short discussion of relevant principles, and continues with a compilation and review of experimental data, covering the same independent variables as the force section. The report ends with a concise summary of general behavior for parallel motion tools.

REMOTE SENSING OF ACCUMULATED FRA-ZIL AND BRASH ICE IN THE ST. LAWRENCE RIVER.

LABORATORY INVESTIGATION OF THE ME-CHANICS AND HYDRAULICS OF RIVER ICE JAMS.

Tatinclaux, J C., et al, Apr 1977, 45p., ADA-032 471,

Lee, C L, Wang, T.P., Nakato, T., Kennedy, J.F.

ICE JAMS, ICE MECHANICS, ICE COVER STRENGTH, COMPRESSIVE PROPERTIES, ICE FLOES, ICE CONDITIONS, EXPERIMENTAL DATA

This report presents experimental results on the conditions

of constricted passage to channel width and is proportional to a negative power of the ratio of floe length to width of constricted passage. The coefficient of proportionality and the negative exponent of this power function appear to be dependent upon the ratio of floe length to floe thickness and to be strongly affected by the properties of the maternal of the laboratory floes, in particular by the interparticle friction or cohesive characteristics. From energy analysis of floe submergence, a relationship between the thickness of a jam formed by accumulation and submergence of floes and the approach flow characteristics was derived and found to fit the experimental data satisfactorily. The relationship predicts that a stable jam cannot be formed when the approach flow velocity exceeds a certain value. This phenomenon was observed experimentally, and the measured maximum values of approach velocity were found to be in excellent agreement with the predicted values. In both studies on jam initiation and development, it was found that surface tension, and therefore the wetting properties of the maternal used for small laboratory floes, have a significant effect on the submergence velocity of small floes, and should be taken into consideration when small-scale laboratory investigations of ice jam phenomena are conducted using floes made of artificial maternal. Experiments on compressive strength floating, fragmented ice covers were conducted for ranges of cover length and cover thickness, using three different floes shapes and sizes. It was found that the compressive strength was inversely proportional to compressive order thickness and floe shape of size remains unclear partly because of the intented ranges of the chees and floe size investigated and partly because of the experimental scatter in the results CR 77-10. ICE FORCES ON VERTICAL PILES.

Nevel, D.E, et al, Apr. 1977, 9p., ADA-051 770, 16 refs

Perham, R.E., Hogue, G B

ICE PRESSURE, PILE STRUCTURES, ICE BREAKING, ICE LOADS, ICE COVER THICK-ICF NESS, AIR TEMPERATURE.

NESS, AIR TEMPERATURE.

The amount of force that an ice sheet can apply to a vertical pile was tested by lowering a hydraulic ram device into a hole cut in an existing ice sheet. The device had a large base and shoved a relatively narrow vertical pile in a horizontal direction. Test variables were pile widths—15 in to 36 7 in, pile shapes—flat, round, 45 deg and 90 deg wedges; ice thickness—26 in to 8.8 in, and ram speed—0.07 in./sec to 18.75 in/sec, but not all shapes and sizes were tested at all speeds. Air temperature was 20F (-6.7C)—Forces and displacements were measured electronically—The findings are presented as a table of test results and as bar graphs of the resultant ice pressures versus the pile width-to-ice-thickness ratio, pile width and shape combination and and pile velocity—The types of failures in the ice sheet were classified as crushing, splitting, buckling, bending, and creeping—The ice sheet generally withstood a high initial load followed by several lower peak load levels—The maximum ice pressure measured was 610 psi for a 12.6-in.-diam round pile in 8.4-in-thick ice CR 77-11 CR 77-11

OBSERVATION AND ANALYSIS OF PROTECT-ED MEMBRANE ROOFING SYSTEMS.

ROOFS, HEAT LOSS, THERMAL INSULATION, THERMAL PROPERTIES, COLD WEATHER CONSTRUCTION, CLIMATIC FACTORS, TESTS, EFFECTIVENESS.

EFFECTIVENESS.

Two performance indicators, effectiveness and thermal efficiency, are defined and used to evaluate the year-round performance of three protected membrane roofs in Alaska and New Hampshire Effectiveness is a measure of the deviations of ceiling temperatures from a yearly average, with large deviations indicating erratic performance in the roofing-insulation system and small departures indicating a thermally stable system. Thermal efficiency, the ratio of calculated heat loss to measured heat loss, is affected by climatic conditions such as rain, snow, solar radiation and wind. Thermal efficiency values of 100% or greater are possible since the calculated heat loss is based only on the inside and outside air temperature differences and the thermal properties of her roof components. Results of the year-round evaluation indicate that the three protected membrane roofs generally have high values of both effectiveness and thermal efficiency. CR 77-12

ROOF LOADS RESULTING FROM RAIN-ON-

Colbeck, S.C., May 1977, 19p., ADA-040 536, 11 refs

ROOFS, SNOW LOADS, LOADS (FORCES), DRAINAGE, RAIN, ANALYSIS (MATHEMAT-

A computer program to calculate the increased live load on a snow-covered toof due to rain-on-snow is given. For the 25-year rainstorm falling on a heavy snow load on a flat roof in Hanover, New Hampshire, an additional 98 kg/sq m (20 lb/sq ft) of liquid water is added to the live load. The additional load due to rain-on snow is very sensitive to the snow properties and characteristics of the roof. A wide range of live loads is possible, depending on the particular circumstances.

REMOTE SENSING, AERIAL SURVEYS, URBAN PLANNING, UNITED STATES—MASSACHUSETTS—BOSTON.

URBAN PLANNING, UNITED STATES—MAS-SACHUSETTS—BOSTON.

The cost effectiveness of remote sensing techniques was compared to that of the conventional techniques used by the U.S. Army Engineer Division, New England, in the Boston Harbor-Eastern Massachusetts Metropolitan Area study A total of 6 level 1, 18 level II, and 18 level III land use categories were mapped from NASA RB-57/RC-8 high altitude aircraft photography for six selected 7.5 minute quadrangles located in the Boston area Watershed and political boundaries could not be mapped from the NASA photography Imperious surfaces and curb lengths were mapped from low altitude aircraft photography obtained with a Zeiss RMK 15/23 camera system (measured scale 1.3500) for two sites in the Boston South and Newton quadrangles The remote sensing procedures used in this study usually provided much greater detail than conventional procedures. The remote sensing procedures were not always cost-effective when compared to the conventional procedures, but they were always more accurate. Therefore, remote sensing techniques should be used and appropriate photographic resolution and scale factors taken into consideration when mapping land use, curb density and impervious surfaces for use in the STORM (storage, treatment, overflow, runoff) model

CR 77-14 ICE BREAKUP ON THE CHENA RIVER 1975

ICE BREAKUP, RIVER ICE, DAMS, BRIDGES, FLOOD CONTROL, ICE COVER THICKNESS, ICE VOLUME, UNITED STATES—ALASKA— CHENA RIVER.

CHENA RIVER.

The breakup of the Chena River was observed and documented during the spring of 1975 and 1976. This study attempted to determine the potential for damage to the proposed Chena River flood control dam from ice and debris during breakup. Results of this study were compared to those of a 1974 companion study. In 1975, ice thicknesses were determined to be 15% thinner than in 1974 and ice volume was 33%, smaller. No major ice floes were observed in 1975 and no significant flooding occurred, although the approaches to a bridge at the damsite were eroded by debris and high water immediately after breakup. The 1976 breakup was milieer than that of 1975. Minor flooding in the lower river was caused by jamming of a few large ice pieces, but no property damage resulted.

EXPERIMENTAL SCALING STUDY OF AN ANNULAR FLOW ICE-WATER HEAT SINK.

ICE WATER INTERFACE, HEAT TRANSFER, UNDERGROUND FACILITIES, HEAT RECOV-ERY, COOLING SYSTEMS, MODELS, COMPUT-ERIZED SIMULATION.

ERIZED SIMULATION.

A laboratory experimental study was conducted on a scale model of an annular flow ice-water heat sink to be used to store the waste heat produced in a hardened defense installation operating in an isolated mode. The study examined 1) scaling relationships for predicting the performance of prototype units using data from scale models, 2) the accuracy of a computer prediction technique developed during an earlier study, 3) the heat transfer phenomenon at the ice-water interface, and 4) some practical aspects related to the operation of a prototype installation. The scaling relationships and the computer program were found to be sufficiently accurate for use in developing a prototype vink design. During operation the scale model sink provided an almost constant low temperature source of coolant water an almost constant low temperature source of coolant water for approximately one-half its useful life and thereafter behaved like an ordinary stored water reservoir type heat sink. No significant operational problems were discovered.

CR 77-16 ICEBREAKER SIMULATION.

Nevel, DE, July 1977, 9p. ADA-044 109, 6 refs.

ICEBREAKERS, ICE BREAKING, ICE NAVIGATION, MATHEMATICAL MODELS, SIMULA-TION.

A brief discussion is given of the ways an icebreaker breaks A brief discussion is given of the ways an icebreaker breaks ice. Since the icebreaking process is so complex, the solution of a mathematical model does not appear to be feasible. As an alternative, it is suggested that physical models be used to design icebreakers. The appropriate scaling laws for physical models are developed and their practical limitation discussed. ICE ACCUMULATION ON OCEAN STRUC-TUBES

Minsk, L.D., Aug. 1977, 42p., ADA-044 258, Bibliog-

ICE ACCRETION, ICE FORMATION, SHIP IC-ING, ICE PREVENTION, ICE REMOVAL, SEA SPRAY, AIR TEMPERATURE, WATER TEMPERATURE, WHID FACTORS, FREEZING

A literature search was made for information on the accretion of ice on ocean structures and on methods for control. The bulk of the reports were in Russian, with some additional Japanese, British, American, Canadian, and Icelandic sources. Analysis of icing reports indicated that sea spray is the most important cause of ship icing, with lesser amounts due to freezing rain, snow, and fog. Icing is a potential danger whenever air temperatures are below the freezing point of water and the sea temperature is 6C or lower Theoretical work on the ice accretion process is discussed, and a method is suggested, based on Russian experiments, for calculating the sea spray accumulation rate for cylindrical and flat surfaces as a function of water source temperature, are temperature, and wind speed. Other factors that influence icing seventy are ship size and configuration, angle between ship course and water heading, and ship speed Icing in the north temperate latitudes generally occurs in the rear of barometric depressions. Maps showing limits of various degrees of icing seventy are included. Atmospheric icing measurements on tall land-based structures are presented, and potential maximum accumulations estimated. Control measures are discussed, though no completely effective A literature search was made for information on the accretion ed, and potential maximum accumulations estimated. Control measures are discussed, though no completely effective method is available Mechanical (impaction) methods are the most common, but experiments have been conducted on heated, icephobic, and deformable surfaces, and with freezing point depressants. No device for the unequivocal measurement of ice accumulation is available, though some experimental methods are suitable for controlled testing; it is recommended that a device be developed.

ICE ARCHING AND THE DRIFT OF PACK ICE THROUGH RESTRICTED CHANNEL

Sodhi, D.S., Aug. 1977, 11p., ADA-044 218, 23 refs. 32-1156

PACK ICE, SEA ICE, DRIFT, CHANNELS (WA TERWAYS), ICE JAMS, MATHEMATICAL MODELS.

Models originally developed to describe the arching and Models originally developed to describe the arching and the movement of granular materials through hoppers or chutes are applied to the arching and drift of pack ice in straits and gulfs having lengths of 50 to 500 km. Verification of the usefulness of the models is attempted by making comparisons with ice deformation patterns as observed via satellite imagery in the Bering Strait region and in Amundsen Gulf. The results are encouraging in that there is good correspondence between observed arching and lead patterns and those predicted by theory. In addition, values determined via the model for the angle of internal friction (approx 30 deg to 35 deg) and the cohesive strength per unit thickness (approx 2,000N/m) are similar to values obtained by other approaches. It is estimated that if the wind velocity parallel It is estimated that if the wind velocity parallel Strait exceeds approx 6 m/s, there will be Bering Strait exceeds approx 6 m/s, there through the strait

MECHANICS OF CUTTING AND BORING. PART 6: DYNAMICS AND ENERGETICS OF TRANSVERSE ROTATION MACHINES.

Mellor, M., Aug 1977, 36p, ADA-045 127, 3 refs 32-1157

ROCK DRILLING, EXCAVATION, ICE CUT-TING, DRILLS, PERMAFROST, DESIGN.

The report deals with forces and power levels in cutting machines having a disc or drum that rotates about an axis perpendicular to the direction of advance. The forces on individual cutting tools are related to position on the rotor and to characteristics such as tool layout, rotor speed, rotor size, machine advance speed, and rotor torque. rotor size, machine advance speed, and rotor torque. Integration leads to expressions for force components acting on the rotor axis, taking into account tool characteristics, cutting depth of the rotor, and rotor torque estimates of tractive thrust and thrust normal to the primary free surface. For self-propelled machines, this leads to considerations of traction, normal reaction, weight and balance, and power/weight ratios. Specific energy consumption is analyzed and related to machine characteristics and strength is analyzed and related to machine characteristics and vitingin of the material being cut. Power per unit working area is discussed, and data for existing machines are summarized Power requirements for ejection of cuttings are analyzed, and the hydrodynamic resistance on underwater cuttings is treated. A number of worked examples are given illustrate the principles discussed in the report

INVESTIGATION OF AN AIRBORNE RESISTIVITY SURVEY CONDUCTED AT VERY LOW FREQUENCY.

Arcone, S A., Aug 1977, 48p., ADA-044 684, Bibliog-

raphy p.44-45. 32-1158

AERIAL SURVEYS, REMOTE SENSING, AIR-BORNE RADAR, ELECTRICAL RESISTIVITY, GEOLOGIC STRUCTURES, VERY LOW FRE-QUENCY, GEOPHYSICAL SURVEYS, SUBSUR-FACE INVESTIGATIONS, UNITED STATES— MAINE-ALLAGASH.

An airborne survey of earth electrical resistivity, computed from the complex tilt of the electric field vector of a VLF from the complex tilt of the electine field vector of a VLF (178 kHz) radio surface wave, has been studied. The survey was conducted at a 150-m mean flight altitude. The bedrock of the survey area was slate containing an igneous stock. Topography was found to distort the resistivity contours through its effect upon the vertical component of the electric field. At 300-m flight altitude most resistivity information was retained due to the deterioration of topographic influence. The phase of the tilt, which cannot be distinguished from the amplitude by an airborne antenna system, was determined from a ground survey of the surface impedance and was found to be an important influence on the airborne detection of high resistivity areas. The entire 150-m survey was reevaluated with topographic effects removed. The resolution of the igneous geology improved and several of these improvements were verified by the ground measurements.

MID-WINTER INSTALLATION OF PROTECT-ED MEMBRANE ROOFS IN ALASKA Aamot, H.W.C., Aug. 1977, 5p., ADA-045 356, 2 refs.

THERMAL INSULATION, WEATHER CONSTRUCTION, COST ANALYSIS,

WEATHER CONSTRUCTION, COST ANALYSIS, UNITED STATES—ALASKA.

Cold weather limits the successful application of built-up roofing, but often a roof installation must be completed late in the fall or in the winter The loose-lad protected membrane roof with a synthetic sheet membrane can be installed in the middle of the winter with complete reliability. A synthetic membrane is traditionally more expensive than built-up roofing (rising crude oil prices, however, have reversed this condition), but it has two special features besides its suitability for winter installation it can be placed on a damp deck, if necessary, and, being loose-laid, it does not split because of deck movement This report documents information on the installation of two roofs in Anchorage, Alaska, during January and February 1972, including a discussion of the necessary snow removal from the bare deck and the use of portable shelters for preparing the lap joints between sheets during very cold weather. The winter installation caused no special construction problems and the advantages of the synthetic membrane make it an attractive alternative to built-up roofing The cost of loose-laid protect-de membrane roofs in Alaska was, in 1972, nearly 3300 per square (\$28/sq m), including insulation Prices are rising as labor costs rise and as more insulation is specified. Distribution limited to U.S. Gov't agencies only.

MILITARY EQUIPMENT, SOIL STRENGTH, STATIC STABILITY, FOUNDATIONS.

STATIC STABILITY, FOUNDATIONS.

The results of field test programs conducted to evaluate the performance of several prototype baseplates on sand and clay soils are presented. One test series was accomplished to develop a possible alternative baseplate for the 60-mm Lightweight Company Mortar System (LWCMS). Three prototype baseplates were used in this series which resulted in design recommendations for a very lightweight, three-spade baseplate for use with the LWCMS. Another part of the program consisted of design and testing of a rototype baseplate for use with the LWCMS another part of the program consisted of design and testing of a rototype baseplate for use with an improved 81-mm mortar. part of the program consisted of design and testing of a prototype baseplate for use with an improved 81-mm mortar system. Design goals, which were verified in the test program, were to provide a displacement reduction of up 50% and substantial reductions in tilt relative to the present M3 baseplate Results obtained using a baseplate test fixture having spades of variable depth and configuration indicated that spade depth was very important on sand but of minor influence on clay. The influence of spade depth on displacement and tilt in both three- and four-spade configurations is covered in detail. Some data on the influence of socket height and perforation pattern on performance are also included

COLLABORATION OF ARCHITECT A BEHAVIORAL SCIENTIST IN RESEARCH AND

Ledbetter, CB, Aug. 1977, 8p., ADA-045 418, 33 refs.

COLD WEATHER CONSTRUCTION, BUILD-INGS, ENVIRONMENTS, PROFESSIONAL PER-SONNEL, RESEARCH PROJECTS, HOUSES

This report discusses the relationship between an architect and a behavioral scientist. Some of the discussion applies

to this cooperative work for design of buildings. The bulk, however, relates to the cooperation of architect and behavioral scientist while conducting research. Examples from collaborative research at Alaskan military installations cited which demonstrate the roles and contributions

EVALUATION OF EXISTING SYSTEMS FOR LAND TREATMENT OF WASTEWATER MANTECA, CALIFORNIA, AND QUII OUINCY. WASHINGTON.

WASTE DISPOSAL, GROUND WATER, SOIL
CHEMISTRY, LAND DEVELOPMENT, WATER
TREATMENT, ENVIRONMENTAL IMPACT.

TREATMENT, ENVIRONMENTAL IMPACT. Wastewater disposal sites at Mantees, California, and Quincy, Washington, were evaluated for their current performance and for the long-term impact of wastewater application. These sites have been operated as slow-infilitation, land-disposal systems for up to 20 years. Current performance was evaluated in terms of water quality, while soil chemical parameters were measured to determine the effects of prolonged wastewater application at the sites. No significant effects on the performance were found to be due to differences in pretreatment. A difference between the performances of the two sites was attributed mainly to management practices. effects on the performance were found to be due to differences in pretreatment. A difference between the performances of the two sites was attrabuted mainly to management practices, site history and climatic differences. While leaching of nitrate was observed at both sites, the impact on groundwater quality generally was found to be within the accepted limits (less than 10 mg/l of NO3-N). Leaching of phosphorus to a depth of 150 cm was found at both sites but was higher at Manteca. This was thought to be due to p.oblems associated with crop menagement, land use, and mode and schedule of wastewater application. Total and extractable phosphorus increased in the surface soil layers with time However, soil nitrogen appeared to decrease, probably because of mineralization. Soil organic matter and cation exchange capacity increased. Some increase in exchangeable Na was noted, but not enough to produce alkaline or saline conditions. A drop in soil pH at Quincy after prolonged application is thought to have been due to removal of carbonates by leaching and by H+ from nitrification. If these disposal areas were managed as treatment sites, leachate quality should meet proposed Environmental Protection Agency guidelines for drinking waters.

ICE LOADS, LOADS (FORCES), ICE PRESSURE, WEDGES, ANALYSIS (MATHÉMATICS), THEO-

A theory for ice forces acting on inclined wedges has been developed, thus making it possible to predict the magnitude of the intermittent ice forces from knowledge of the physical parameters of the system. The theory has been verified by model tests with artificial and natural ice

OBSERVATIONS OF THE ULTRAVIOLET SPECTRAL REFLECTANCE OF SNOW.

O'Brien, H.W., Oct. 1977, 19p, ADA-046 349, 11 refs.

SNOW OPTICS, REFLECTIVITY, SPECTROPHO-TOMETERS, ULTRAVIOLET RADIATION

The spectral reflectance of natural snow in the range of 0.20- to about 0.40-micron wavelengths was studied in the laboratory using both continuous spectral scanning and fixed bandpass measurements. White barium sulfate pressed powder was used as a standard for comparison. The reflectance uer was used as a standard for comparison. The reflectance of fresh snow was found to be very high (usually nearly 100%) and only weakly wavelength dependent from 0.24 micron to the visible range. In the 0.20- to 0.24-micron of the spectrum, the reflectance was found to be quite erratic. Possible reasons for the irregularities in reflectance measurements are discussed. FREEZE-THAW TESTS OF LIQUID DEICING CHEMICALS ON SELECTED PAVEMENT MATERIALS.

Melior, M. 32-3536

ICEBERG TOWING, ICE (WATER STORAGE), ENGINEERING.

ENGINEERING.

Many of the technical questions relating to iceberg transport are given brief, but quantitative, consideration. These include iceberg genesis and properties, the mechanical stability of icebergs at sea, towing forces and tug characteristics, drag coefficients, ablation rates, and handling and processing the iceberg at both the pick-up site and at the final destination. In particular, the paper attempts to make technical information on glaciological and ice engineering aspects of the problem more readily available to the interested planner or engineer Specific conclusions include. 1) No unprotected iceberg, no matter how long or wide, would be likely to survive the ablation caused by a long trip to low latitudes 2) leebergs that have a horizontal dimension exceeding 2 km may well be prone to breakup by long wavelength swells 3) To avoid the dangers associated with an iceberg capsizing, the width of a 200-m-thick iceberg should always be more than 300 m 4) For towing efficiency the length/width ratio of a towed iceberg should be appreciably greater than unity 5). For a pilot project, the selected iceberg would have to be quite small, if for no other reason than the practical availability of tug power (Auth.)

ICE SHEETS, ICE ELECTRICAL PROPERTIES, ICE PHYSICS, RADIO ECHO SOUNDINGS, DIE-LECTRIC PROPERTIES, ICE COVER THICK-NESS, ICE DENSITY, ANTARCTICA—FOLGER, CAPE

Measured physical properties of core to bedrock taken at Cape Folger, East Antarctica, are used to compute a profile of dielectric properties and from this, a depth-reflection coefficient profile for comparison with the observed radio-cellections. The measurements available on physical properties are density variations, bubble size and shape changes, and crystal fabric variations. The close correspondence between the depths of the bubble shape changes (which are definitely deformational features), and the depths of the density variations, and between both of these and the radio echo layers indicates that deformational events in the ice sacet's history are represented by the variations in the physical property and associated radio-echo records. CR 78-05 VISCOELASTIC DEFLECTION OF AN INFI-NITE FLOATING ICE PLATE SUBJECTED TO A CIRCULAR LOAD.

Takagi, S., Apr. 1978, 32p., ADA-054 896, 19 refs. 32-4367

FLOATING ICE, PLATES, VISCOELASTICITY, LOADS (FORCES), ANALYSIS (MATHEMAT-ICS).

ICS).

The viscoelastic deflection of an infinite floating ice plate subjected to a circular load is solved, assuming the Maxwell-Voigt type four-element model. An effective method is developed for numerical integration of the solution integrals, of which each integrand contains a product of Bessel functions extending to infinity. The theoretical curve is fitted to the field data, but the material constants thus found varied with time and location.

IN-PLANE DEFORMATION OF NON-COAXIAL PLASTIC SOIL.

Takagi, S., Apr. 1978, 28p., ADA-054 217, 28 refs. 32-3962

THEORIES, SOIL CREEP, PLASTIC DEFORMA-TION, BOUNDARY VALUE PROBLEMS

TION, BOUNDARY VALUE PROBLEMS

The theory of non-coaxial in-plane plastic deformation of soils that obey the Coulomb yield criter on is presented. The constitutive equations are derived by use of the geometry of the Mohr circle and the theory of characteristic lines it is found that, for solving a boundary value problem, the non-coaxial angle must be given such values that enable us to accommodate the presupposed type of flow in the given domain satisfying the given boundary conditions. The non-coaxial angle is contained in the constitutive equations as a parameter. Therefore, the plastic material obeying the Coulomb yield criterion is a singular material whose constitutive equations are not constant with material but are variable with flow conditions.

CR 78-09 INTERACTION OF A SURFACE WAVE WITH A DIELECTRIC SLAB DISCONTINUITY

Arcone, S.A., et al, Apr. 1978, 10p., ADA-055 956, 15

32-4369 ICE ELECTRICAL PROPERTIES, DIELECTRIC PROPERTIES, WAVE PROPAGATION, ELECTRIC FIELDS, MICROWAVES, AIRCRAFT ICING, HELICOPTERS, ICE REMOVAL.

The interaction of a 5 1-GHz transverse electric surface wave with a dielectric slab is experimentally investigated. The wave is initially supported by a dielectric substrate resting upon a metallic ground-plane. A slab, made of the same dielectric material as the substrate and variable is height, is then placed upon the waveguide. The results for a small slab sitting on the substrate showed that the discontinuity was a very inefficient launcher of reflected surface waves Investigations of these reflections with a trough waveguide showed that, for values of slab height comparable to the exponential decay height of the surface wave, the effections remain very small. However, as the slab height is increased beyond the decay height of the surface wave, the effections remain very small. However, as the slab height is increased beyond the decay height, the reflected amplitude approaches the theoretical value for a plane wave reflected from the interface between air and the same dielectric. The results are applicable to surface wave methods of microwave deicing of wings and helicopter rotors. The interaction of a 5 1-GHz transverse electric surface wave

Shaw, K.A., Lemieux, G.

WET SNOW, SNOW COMPRESSION, SNOW WATER CONTENT, VISCOSITY, SALINITY, SNOW MELTING, STRESSES, IONS.

SNOW MELTING, STRESSES, IONS.

The compressibility of wet snow is described in terms of pressure melting and nonlinear viscous deformation at grain contacts. The results of experiments with different salinities and liquid water contents are compared with computed densities. The decreasing compressibility of wet snow with increasing salinity and decreasing liquid content is quantified and explained. Simultaneous particle growth and the doubly charged layer at phase boundaries are included in the model. The results snow that the density of wet snow increases approximately as a power of time but is highly dependent on the stress, initial particle size, liquid water content, and ionic impurity content of the srow.

MECHANICS OF CUTTING AND BORING. PART 8: DYNAMICS AND ENERGETICS OF CONTINUOUS BELT MACHINES.

Mellor, M., Apr. 1978, 24p., ADA-055 247.

ROCK EXCAVATION, BOREHOLE INSTRU-MENTS, ROCK DRILLING, EXCAVATION, ICE CUTTING, MACHINERY, PERMAFROST, DE-

The report deals with forces and power requirements for cutting machines of the belt type, as exemplified by large chain saws and ladder trenchers. The forces of single cutting tools are considered, and related to the overall forces cuting tools are considered, and related to the overall forces on a cutter bar Forces are related to power, and sources of loss are identified Tractive thrust and normal reaction are analyzed and used to assess the traction, weight and balance factors for self-propelled machines Specific energy consumption and performance index are treated, and concepts of power density and apparent belt pressure are introduced Requirements for acceleration of cuttings are assessed, and the report concludes with a set of worked examples

SOIL WATER MIGRATION.

Road test sections of membrane-enveloped silt and clay soils overlain with asphalt cement concrete were subjected to repetitive dynamic plate-bearing loadings to determine their strength variations during freeze-thaw cycles. The recoverable surface deformations in the load deflection bowl were continuously measured during the loading cycles and analyzed, using the Chevron layered clastic computer program to obtain the in situ resilient deformation modulus of the various section layers at different stages of the freeze-thaw cycles. The resilient stiffness of the pavement system (the total load per unit of resilient load plate deflection) was also calculated for the various freeze-thaw conditions. The modulus values of the asphalt cement concrete varied inversely with its temperature by an order of magnitude (90,000 psi). The resilient stiffness of the pavement system varied in the same manner by nearly a factor of eight (2284 kipy/in). The resilient stiffness of the pavement system varied in the same manner by nearly a factor of eight (2284 kipy/in). The resilient stiffness of the pavement system varied in the same manner by nearly a factor of eight (2284 kipy/in). Despite the wide strength variations of the sections during freeze-thaw cycles, membrane-enveloped fine-grained soils can be utilized instead of granular materials as base and subbase layers in flexible pavements in cold regions where moisture augration is a major concern. Moisture migration did not occur at saturation levels up to 75°c, thus there was no strength loss during thawing. loss during thawing

Gow, A.J.

33-1520

SEA ICE, FAST ICE, ICE CRYSTAL STRUCTURE, OCEAN CURRENTS

Field observations of the growth fabrics of the fast and near-fast ice along the coasts of the Beaufort and Chukchi Seas show that at depths of more than 60 cm below the upper ice surface, the sea ice crysta's show striking alignments

within the horizontal plane. In general, the c-axes of the crystals were aligned roughly E-W parallel to the coast In the vicinity of islands the alignment roughly paralleled the outlines of the islands, and in narrow passes between islands the alignment paralleled the channel Our observations, as well as similar observations made in the Kara Sea by Cherepanov, can be explained in it is assumed that the c-axes of the crystals are aligned parallel to the "long-term" current direction at the sea ice/sea water interface. The alignments are believed to be the result of geometric selection among the growing crystals, with the most favored orientation being that in which the current flows normal to the plates of ice that make up the dendritic ice/water interface characteristic of sea ice.

BUCKLING PRESSURE OF AN ELASTIC PLATE FLOATING ON WATER AND STRESSED UNIFORMLY ALONG THE PERIPHERY OF AN INTERNAL HOLE.

Takagi, S., June 1978, 49p., ADA-056 585, 10 refs. 32-4408

FLOATING ICE, ICE STRENGTH, BOUNDARY VALUE PROBLEMS, ANALYSIS (MATHEMAT-ICS).

The analytical solution and the numerical study of the eigenval-The analytical solution and the numerical study of the eigenvalue problem for determining the buckling pressure of an infinite elastic plate floating on water and stressed uniformly along the periphery of an internal hole is presented. The boundary conditions considered are the clamped-, simple-, and free-edge conditions Small buckling pressure occurs only for the free-edge condition. The shape of the deflection for the free-edge condition suggests that buckling is an important mechanism of failure

ON THE DETERMINATION OF HORIZONTAL FORCES A FLOATING ICE PLATE EXERTS ON A STRUCTURE.

Kerr, A.D., Aug. 1978, 9p., ADA-060 444, 26 refs. For this report from a different source see 32-4451.

FLOATING ICE, ICE PRESSURE, LOADS (FORCES), OFFSHORE STRUCTURES, ICE STRENGTH

This report first discusses the general approach for calculating horizontal forces an ice cover exerts on a structure lice force determination consists of two parts (1) the analysis of the in-plane forces, assuming that the ice cover remains intact, and (2) the use of a failure criterion, since an ice force cannot be larger than the force capable of breaking up the ice cover. For an estimate of the largest ice force cannot be larger than the force capable of breaking up the ice cover For an estimate of the largest ice force, an elastic plate analysis and a failure criterion are often sufficient A review of the literature revealed that, in the majority of the analyses, it is assumed that the failure load is directly related to a "crushing strength" of the ice cover However, observations in the field and tests in the laboratory show that in some instances the ice cover fails by buckling This report reviews the ice force analyses based on the buckling failure mechanism and points out their shortcomings. The report then presents a new method of analysis which is based on the buckling mechanism.

HYDRAULIC MODEL INVESTIGATION OF DRIFTING SNOW.

Wuebben, J.L. June 1978, 29p., ADA-059 175 33-1767

HYDRAULIC STRUCTURES, SNOWDRIFTS. MODELS, BOUNDARY VALUE PROBLEMS, SNOW FENCES.

A model investigation of drifting snow conditions was conducted in a hydraulic flume using a sand-water analog. Model results were evaluated to define modeling parameters that would allow quantitative correlation between measured prototype drift conditions and the model. Models of the fence were constructed for three heights and two geometric scales Geometric scaling was based on terrain roughness and boundary layer thickness considerations, while velocity scaling was based on particle fall velocity and threshold of motion characteristics. Simulation of the atmospheric boundary layer was found to be of primary importance. Velocity scaling analysis suggested the use of a significant wind concept. A model investigation of drifting snow conditions was conduct teristics Simulation of the atmospheric boundary lays was found to be of primary importance. Velocity scalin analysis suggested the use of a significant wind concepbased on a combination of velocity magnitude and frequency Similarity of precipitation rate was not essential, and could be altered within limits to adjust the time scale

SHORELINE CHANGES ALONG THE OUTER SHORE OF CAPE COD FROM LONG POINT TO MONOMOY POINT.

Gatto, L.W., July 1978, 49p., ADA-060 297, 52 refs

SHORELINE MODIFICATION, AERIAL SUR-VEYS, PHOTOINTERPRETATION

VEVS, PHOTOINTERPRETATION

This investigation utilized historical and recent aerial photographs and satellite imagery in 1) estimating changes in positions of the high-water line and sea cliff break and base in rates of accretion and or errosion, and in volumes of transported sediment, and 2) providing a preliminary evaluation of the direction of litteral transport along the ower Cape Cod coast. This investigation has illustrated a photointerpretation technique that is useful in performing a reconsistsment of coastal change. The data obtained from this method can be used to supplement those acquired by ground

surveys and are valid as first approximations for planning subsequent, more detailed surveys.

ESTUARINE PROCESSES AND INTERTIDAL HABITATS IN GRAYS HARBOR, WASHINGTON: A DEMONSTRATION OF REMOTE SENS-ING TECHNIQUES

ESTUARIES, SHORELINE MODIFICATION, REMOTE SENSING, AERIAL SURVEYS, SPACE-BORNE PHOTOGRAPHY, TIDAL CURRENTS, SEDIMENTATION, MAPPING.

SEDIMENTATION, MAPPING.
The primary objective of this project was to demonstrate the utility of remote sensing techniques as an operational tool in the acquisition of data required by the U.S. Army Corps of Engineers, Seattle District, in the Grays Harbor dredging effects project, and related projects. Aerial imagery was used to map surface circulation and suspended sediment patterns near the hopper dredge pump site at the harbor entrance and near pulpmill outfails in Aberdeen, and to map the areal distribution and extent of intertidal habitats. The surface circulation maps, prepared from the aerial photographs and thermal imagery, compared favorably with the large-scale circulation patterns observed in the Grays Harbor hydraulic model at the U.S. Army Engineer Waterways Experiment Station.

Of the imagery provided by NASA, the thermal imagery was more useful than the color or color infrared (CIR) photographs for mapping circulation, while the CIR photographs were more useful than the thermal imagery or the color photographs for mapping intertidal habitats. Current velocities estimated from dye dispersion patterns and drifting dye drogues were comparable at some habitats Current velocities estimated from dye dispersion patterns and drifting dye drogues were comparable at some location to velocities measured by in situ current meters and in the hydraulic model Based on a cursory evaluation of LANDSAT-1 imagery acquired in January, February, and October 1973, it had limited utility in providing data on surface circulation patterns in Grays Harbor

CR 78-19 PRIMARY PRODUCTIVITY IN SEA ICE OF THE WEDDELL REGION.

Ackley, S.F., et al, July 1978, 17p, ADA-059 344, 24 refs.

Taguchi, S., Buck, K R. 33-1524

SEA ICE, ICE CORES, BIOMASS, WEDDELL

Physical and biological measurements were made of sea icc cores taken from 685 to 785 in the Weddell Sea. Fluorissicance measurements indicated an algal community that was strongly associated with salinity maxima within the icc. Maximum concentration of chlorophyll a ranged from 030 to 454 mg/stere. Comparisons with the water column standing crop indicated that the standing crop within the icc represents a minor but significant percentage of the total standing crop for the region. The ice algal community is apparently distinct from others that have been described for land-fast ice in McMurdo Sound, sea ice in the Arctic and pack ice off East Antarctica. The highest concentrations of biological material are found in the bottom or top of the sample in those regions, whereas the Weddell Sea samples are concentrated at intermediate depths (65 m to 215 m) within the ice. A qualitative model indicating the relationship between thermally-induced brine migration and subsequent algae growth is presented. This model, indicates the distribution of algae within the ice is dependent on the unique thermal and physical setting for Weddell Sea pack ice where brine drainage processes are initiated by spring and summer warming, but are not carried through as completely as in other regions. (Auth.)

MEASUREMENT AND IDENTIFICATION OF AEROSOLS COLLECTED NEAR BARROW,

Kumai, M., July 1978, 6p., ADA-058 606, 9 refs 33-1525

AEROSOLS, PARTICLE SIZE DISTRIBUTION, ELECTRON MICROSCOPY.

ELECTRON MICROSCOPY.

Measurements of the concentrations of Aitken nuclei in maritime air were made near Barrow, Alaska, in June 1975, with a modified Nolan-Pollack small-particle detector. The concentrations varied from 50 to 300 particles/cu cm, depending upon meteorological conditions. The mean Aitken nuclei count was 100 particles cu cm for diameters greater than 002 microns. Transmission electron micrographs of activols in maritime air near Barrow were taken. The size range was incasured to be 0.01 to 2.5 microns in diameters with the most frequently observed diameter being 0.04 microns. The volume of the maritime air and the collection efficiency of activol particles on filmed grids for electron microscopy were measured. The activol concentrations were found to be 76 to 101 particles cu, the mean concentration was calculated to be 87 particles cu cm. The acrosol particles in the maritime air were identified by electron microscopy and selected area electron diffraction analysis. About 20 of the acrosol particles were identified, and 80 of the particles were too small for electron diffraction analysis.

ANALYSIS OF THE MIDWINTER TEMPERA-TURE REGIME AND SNOW OCCURRENCE IN

33-4415 AIR TEMPERATURE, SNOWFALL, METEORO-LOGICAL DATA, WEATHER FORECASTING, STATISTICAL ANALYSIS.

STATISTICAL ANALYSIS.
This study investigates the possibility of providing estimates of the time of occurrence and length of the freezing season for any location in East and West Germany by using the average January air temperature (AJAT) as an index. The results indicate that reliable values of the mean freezing index can be obtained from the AJAT relationships which are developed for Germany. This association is further verified using data from the northeastern part of the US, and the AJAT is then used to determine the average starting and ending dates (and hence the probable length) of the freezing season for stations in Germany. The AJAT and the average dates of snowfall occurrence for numerous locations in the US, and Germany are also correlated. Interrelationships between these parameters and the average number of days with snow on the ground for stations up to 3000 m in elevation in Germany are examined.

UNDERSEA PIPELINES AND CABLES IN POLAR WATERS

Mellor, M., Sep. 1978, 34p, ADA-086 161, 19 refs.

Special environmental factors that influence the design, laying and maintenance of undersea pipelines and cables in polar waters are described. Various approaches to the protection of submarine pipes and cables are considered, and prime emphasis is given to burial techniques for shallow water A wide range of methods for trenching and burying are discussed, and technical data are given.

INFLUENCE OF FREEZING AND THAWING ON THE RESILIENT PROPERTIES OF A SILT SOIL BENEATH AN ASPHALT CONCRETE PAVEMENT.

BITUMINOUS CONCRETES, SUBGRADE SOILS, SOIL FREEZING, GROUND THAWING, ELAS-TIC PROPERTIES.

TIC PROPERTIES.

Stress-deformation data for silt subgrade soil were obtained from in-situ and laboratory tests, for use in mechanistic models for design of pavements affected by frost action. Plate-bearing tests were run on bituminous concrete pavements constructed directly on a silt subgrade, applying repeated loads to the pavement surface while the silt was frozen, thawing, thawed, and fully recovered. Repeated-load laboratory traxial tests were performed on the silt in the same conditions. Analysis of deflection data from the in-situ tests showed resilient moduli of the silt as low as 2000 kPa for the critical thawing period, and 100,000 kPa or higher when silt was fully recovered. Analysis of the laboratory tests, which gave moduli comparable to the latter values, showed that resilient modulus during recovery from the thaw-weakened condition can be modeled as a function of the changing moisture content.

CR 78-24 PERFORMANCE OF THE ST. MARYS RIVER ICE BOOMS, 1976-77.
Perham, R.E., Sep. 1978, 13p., ADA-061 431, 5 refs

33-1526

ICE BOOMS, ICE PRESSURE, ICE NAVIGA-TION, COLD WEATHER PERFORMANCE.

ICE BOOMS, ICE PRESSURE, ICE NAVIGATION, COLD WEATHER PERFORMANCE.

The ice booms on the St Marys River at Sault Ste. Marie, Michigan and Ontario, were operated a second winter, 1967-71, under colder conditions, with less water flow, lower water levels, and 25% fewer ships in the river than during the previous year. The ice cover behind the booms remained frozen to shore for longer periods, and the loads registered in the booms were relatively unaffected by ship passages compared with the previous year's activity. As in the previous year, most structural load changes in ook place in the west ice boom and were due to movements of the ice cover immediately upstream of the boom. The cover broke free from shore on three occasions the first and thrd occasions were minor events, but on the second incassion the cover cracked free, the timbers remained troved to it and the boom structure became damaged by the subsequent ice activity. Three anchor line assemblies broke over a period of about 4 hours, the two latter beasks occurred while a ship was operating in the ice. These events point out several factors to be considered in ice booms, such as designing the booms to withstand the action of the solid ice cover as well as the fragmented ice cover, keeping the structures and their assembly simple, and inspecting components and assemblies carefully nents and assemblies carefully

RIVER CHANNEL CHARACTERISTICS AT SE-LECTED ICE JAM SITES IN VERMONT

Gatto, L.W., Oct. 1978, 52p., ADA-061 778, 30 refs. 33-1527

ICE JAMS, CHANNELS (WATERWAYS), REMOTE SENSING, PHOTOINTERPRETA-TION, TOPOGRAPHIC FEATURES, RIVER ICE. REMOTE SENSING, PHOTOINTERPRETATION, TOPOGRAPHIC FEATURES, RIVER ICE. The objectives of this investigation were to describe channel characteristics and geographic settings of ice jam sites from aerial photographic interpretation, to indicate which characteristics may be important in causing ice jams, and to suggest additional uses of serial photographs. Uncontrolled photomosaics of each site were assembled and major river characteristics were delineated on the photomosaics. Characteristics described include man-made structures, falls, rapids, changes in channel depths, channel islands, mid-channel shoals or bars, niver bed material, river sinuosity, meanders, floodplain width, riparian vegetation, and types of development on the floodplain. River channel widths were measured from the photographs along rivers where ground truth data were available for comparison. Lengths of channel riffles and pools were measured along the rivers where variations in river depths were evident on the photographs. Aerial photographs provide a regional perspective for evaluating channel characteristics at an ice jam site and for analyzing the geographic setting at each site during ice-free conditions. Photographs taken after ice jams have formed are useful in monitoring ice jam formation, in analyzing ice characteristics, and in documenting ice jam breakup and movement CR 78-26 CR 78-26

ICE FOG SUPPRESSION USING REINFORCED THIN CHEMICAL FILMS.

McFadden, T., et al, Nov. 1978, 23p., ADA-063 107, 20 refs.

Collins, C.M.

ICE FOG, FOG DISPERSAL, CHEMICAL ICE PREVENTION.

PREVENTION.

Ice fog suppression experiments on the Fort Wainwright Power Plant cooling pond were conducted during the winters of 1974-76. Baseline information studies occupied a sizable portion of the available ice fog weather in 1974-75. Then hexadecanol was added to the pond and dramatically improved visibility by reducing fog generated from water vapor released by the pond at 1-4C. Although this temperature was not low enough to create ice fog, the cold vapor fog created was equally as devastating to visibility in the vicinity of the pond. During the winter of 1975-76, suppression tests were continued, using films of hexadecanol, mixes of hexadecanol and octadecanol, and ethylene glycol monobuty either (EGME). Suppression effectiveness at colder temperatures was studied and limits to the techniques were probed A reinforcing grid was constructed that prevented breakup of the film by wind and water currents. Lifetime tests indicated the EGME degrades much more slowly than either hexadecanol or the hexadecanol-octadecanol mix. The films were found to be very effective fog reducers at warmer temperatures but still allowed 20% to 40% of normal evaporation to occur. The vapor this produced was sufficient contracts was sufficient. temperatures on sain anisone 20.5 to 9.5 thomas exapora-tion to occur. The vapor thus produced was sufficient to create some ice fog at lower temperatures, but this ice fog occurred less frequently and was more quickly dispersed than the thick fog that was present before application of

TEMPERATURE ON THE EFFECT OF TEMPERATE STRENGTH OF SNOW-ICE.

Haynes, F.D., Dec. 1978, 25p., ADA-067 583.

SNOW STRENGTH, ICE STRENGTH, TEMPER-ATURE EFFECTS, TENSILE PROPERTIES, COMPRESSIVE STRENGTH.

Uniaxial compression and tension tests were conducted on Uniaxial compression and tension tests were conducted on polycrystalline snow-ice to determine the effect of temperature on its strength. Test temperatures ranged from -0.1C to -54C. Two machine speeds, 0.847 mm/s and 847 mm/s were used for the constant displacement rate tests. The compressive strength at -54C was about one order of magnitude higher than at -0.1C. The tensile strength at langent and 50° strength moduli are given for the compression tests, while the secant modulus to failure is given for the tension tests. The mode of fracture is discussed and the test results are compared with data from other investigations.

TUNDRA DISTURBANCES AND RECOVERY FOLLOWING THE 1949 EXPLORATORY DRILLING, FISH CREEK, NORTHERN ALAS-KA.

Lawson, D E., et al, Dec. 1978, 81p. ADA-065-192,

Brown, J. Everett, K.R., Johnson, A.W., Komárková, , Murray, D.F., Webber, P.J.

33,2739 HUMAN FACTORS, ENVIRONMENTAL PACT, OIL SPILLS, DAMAGE, EXPLORATION, TUNDRA VEGETATION, REVEGETATION.

A 1949 drill site in the Naval Petroleum Reserve Number 4, Alaska, the I ish Creek Test Well I, was examined in August 1977 to determine the disturbance caused by drilling activities and to analyze the response and recovery of the

vegetation, soils, permafrost, and surficial materials to that disturbance. Man-made disturbances include bladed and unbladed vehicular trails, a winter runway, executions, plings, remains of camp structures, steel drums and other solid waste, and hydrocarbon spills. The most intense and lasting disturbance to the vegetation, soils, and permafrost resulted from bulldozing of surface materials, diesel tuel spills, and rails developed by multiple passes of vehicles. Thermokarst subsidence and thermal erosion, caused by increased thay of permafrost due to disturbance, resulted in the development of a hummocky topography and water-filled depressions at the drill site. Some ice wedges disturbed in 1949 are still metting. Soil disturbance ranges from minor modification to complete destruction of the soil morphology. The effects of hydrocarbon spills are still detectable in the soils. Little of the original vegetation remains in the intensely disturbed area, such as around the drill pad where a grass-dominated community prevails. After 28 years, the v-getation cover is closed over most mesic sites, shallow we sites are well vegetated, and xeric sites, areas of dieselfuel spills and areas of severe erosion remain mostly bare. Pioneering plant species on bare, disturbed areas are members of mature vegetation assembliges from the undisturbed tundra which have high reproductive and dispersal capacities. A hypothetical model of natural revegetation and vegetation recovery is proposed. Vascular plants, bryophytes, and lichens were collected from the Fish Creek site area for the first time. Recommendations on cleanup and restoration of sites are presented. of sites are presented.

CR 79-01 STUDY OF WATER DRAINAGE FROM CO-LUMNS OF SNOW.

Denoth, A, et al, Jan. 1979, 19p., ADA-066 935 Seidenbusch, W., Blumthaler, M., Kirchlechner, P, Ambach, W. 34-1108

SNOW, WATER FLOW, DRAINAGE

Experiments were conducted to study the flow of water through columns of homogeneous, rejacked snow. The gravity flow theory of water flow through snow was verified, although possibly there is some dependence of the relative permeability on the state of metamorphism of the snow Also, at very large values of saturation there may be some additional flow in saturated charnels

CR 79.02 EFFECT OF WATER CONTENT ON THE COM-PRESSIBILITY OF SNOW-WATER MIXTURES. Abele, G., et al, Jan. 1979, 26p., ADA-066 936, 6 refs. Haynes, FD.

SNOW WATER CONTENT, SNOW COMPRESSION, SNOW DENSITY, SNOW DEFORMA-TION.

The stress-density relationships of snow-water mixtures were ine stress-density relationships of snow-water mixtures were investigated and are shown as functions of water content, initial snow density, initial snow-water mixture density and rate of deformation. An increase in water content in snow at a particular density or a decrease in the rate of deformation (or strain rate) decreases the stress, but apparently not the specific energy required to reach a specific mixture density. density.

CR 79-03 BLANK CORRECTIONS FOR ULTRATRACE ATOMIC ABSORPTION ANALYSIS. Cragin, J.H., et al, Jan. 1979, 5p., ADA-066 979, 2

refs.

Quarry, S T. 33-3166

WATER CHEMISTRY, CHEMICAL ANALYSIS, METALS, ATOMIC ABSORPTION.

METALS, ATOMIC ABSORPTION.

Both flame and flameless atomic absorption(AA) measurements require a distilled water blank correction. This correction is due to the analyte contained in the distilled water used to prepare the standards and not, as commonly thought, to the reference "blank" used to zero the instrument Flameless AA analyses of acidified heavy metal samples generally require additional corrections for the furnace deflection blank and for an acid blank. To prevent adsorption losses, the acid blank should be determined by extrapolation of a series of acid dilutions in distilled water.

COMPUTER MODELING OF ATMOSPHERIC ICE ACCRETION Ackley, S.F., et al., Mar. 1979, 36p., ADA-068 582, 25

refs Templeton, M K.

ICE ACCRETION, METEOROLOGICAL FAC-TORS, ICE PHYSICS, HELICOPTERS

TORS, ICE PHYSICS, HELICOPTERS
A computer model is described to compute the amount of ice accretion on an object under a variety of initial conditions. Numerical techniques are best applied to these problems because of time dependent effects governing the amount of ice collected and the variety of initial conditions that can lead to ice accumulation. The helicopter rotor ising problem adds an additional complexity since the velocity along the rotor blade varies over a wide range, strongly affecting the amounts of ice collected at different blade positions. The physics of ice accretion is reviewed, and the accounting for the time-dependence in the computer model is described.

and indicate the dependence of ice accretion on velocity, droplet sizes, cloud liquid water content, and temperature for a cylindrical object of constant size

GROUTING SILT AND SAND AT LOW TEM-PERATURES—A LABORATORY INVESTIGA-

Johnson, R., Mar. 1979, 33p, ADA 068 741, 4 refs. 33-3867

LOW TEMPERATURE TESTS, GROUTING, CHEMICAL REACTIONS, COMPRESSIVE STRENGTH.

This report presents data from an experimental program undertaken to develop information on proposed and existing chemical grout solutions to provide engineering properties in connection with grouting of soils in ambient temperatures of 39 F and below Twelve grout solutions were investigated, including organic chemicals, sodium silicates, cements, and clay (bentonite).

CR 79-06 NONDESTRUCTIVE TESTING OF IN-SERVICE HIGHWAY PAVEMENTS IN MAINE.

Smith, N., et al, Apr. 1979, 22p, ADA-069 817. Eaton, R.A., Stubstad, J. 34-1843

ROADS, COLD WEATHER TESTS. BEARING STRENGTH, FLEXURAL MENTS.

STRENGTH.

Nondestructive repetitive plate bearing (RPB) tests were conducted on various test sections in state highways in Maine during April 13-15, 1976. The RPB test consists of making resilient surface deflection measurements during repetitive loadings at various radii from the load plate. The pavement system stiffness was calculated, and the resilient modulus values for the various pavement layers were determined with the Chevron computer program for a layered elastic system. A thawed analysis using nondimensional deflection curves for the various sections provided a guide to the susceptibility of the pavement systems to surface failure and pothole development. Some companions to surface failure and pothole development. Some companions to surface failure and nonstabilized angiregate and soil were made with calculated stiffness values. The moduli of the various materials were also compared. The residual surface deflections during testing for several pavement systems indicated calculated stiffness values. The moduli of the various materials were also compared. The residual surface deflections during testing for several pavement systems indicated a linear logarithmic relationship with number of load applications. A relationship between the modulus of the aspha't cement concrete pavement and pavement temperature was developed for the limited temperature range during the testing

PENETRATION TESTS IN SUBSEA PERMA-FROST, PRUDHOE BAY, ALASKA. Blouin, S E, et al, May 1979, 45p., ADA-071 999, 9

refs.

Chamberlain, E J., Seilmann, P.V., Garfield, D.E 33-4437

SUBSEA PERMAFROST, BOTTOM SEDIMENT, TESTS, PENETROMETERS, OFFSHORE DRILLING.

Sediments beneath the Beaufort Sea near Prudhoe Bay, Alaska, were probed at 27 sites using a static cone penetrometer to determine engineering properties and distribution of material types, including ice-bonded sediments. The probe provided both point and casing resistance data and thermal profiles. At five sites these data were correlated with information from adjacent drilled and sampied holes. These control data and the quality of the probe information permitted profiles of sediment type and occurrence of ice bonded material to be developed along these lines that included union sensition. data and the quality of the probe information permitted profiles of sediment type and occurrence of ice bonded material to be developed along three lines that included various geological features and depositional environments. Material properties were quite variable in the upper 14 m of sediments probed. In general, softer, finer-grained vediments occurred in the upper layers, while penetration refusal was, but in stiff gravels 10 to 12 m below the seabed. Seabed teriperatures during the study were all below OC. However, because of uncertainties in freezing point values caused by brines, evaluation of the penetration resistance data was required to identify the occurrence of ice-bonded sediments. The coupling of thermal and penetration resistance data revealed that seasonally ice-bonded sediments occurred where the sea ice froze back to or near the seabed. Deeper perennially frozen sediments also appeared to be present at several probe sites. The penetration data obtained can be used to aid in the design of shallow and deep foundations in both ice-bonded and unfrozen subsea sediments.

SEA ICE RIDGING OVER THE ALASKAN CON-TINENTAL SHELF.

Tucker, W B., et al, May 1979, 24p., ADA-070 572, 24 refs

Weeks, W.F., Frank, M

SEA ICE DISTRIBUTION, PRESSURE RIDGES, ICE DEFORMATION, SURFACE ROUGHNESS, PROFILES, LASERS, MATHEMATICAL MODELS, STATISTICAL ANALYSIS, REMOTE SENS-ING. FORECASTING

Sea tee ridging statistics obtained from a series of laser surface roughness profiles are examined. Lach set of profiles consists of six 200-km-long flight tracks oriented approximately perpendicular to the coastline of the Chul-chi and Beaufort.

Scas. The flights were made in February, April, August, and December 1976, and one and ional profile was obtained north of Cross Island during Marc... 1978. It was found that although there is a systematic variation in mean indge leight (h) with season (with the highest values occurring in late winter), there is no systematic spatial variation in at a given time. The number of ndges/km is also high during the late winter, with the highest values occurring in the Barter and Cross Island profiles. In most profiles, the ice 20 to 60 km from the coast is more highly deformed than the ice either nearer the coast or farther seaward. The Wadhams model for the distribution of ridge heights gives better agreement with observed values in the higher indge categories than does the Hibler model. Estimates of the spatial recurrence frequency of large pressure ridges are mad by using the Wadhams model and also by using an extreme value approach. In the latter, the distribution of the largest ridges per 20 km of laser track was found to be essentially normal. Wadhams' distribution consistently profiles.

SEDIMENT TRANSPORT, GLACIAL TILL.
Sedimentation at the terminus of the Matanuska Glacier has been found to be primarily subaerial in a 100- to 300-m wide, ice-cored zone paralleling the edge of the active ice. Certain physical and chemical characteristics of the cand debris of the superglacial, englacial and basal zone of the glacier indicate the debris of the basal zone, the primary source of 5-diment, is entrained during freeze-on of meltwater to the glacier sole. Till formation results from the melting of buried ice of the basal zone. Meltonitude in the sole of the control of the sole of the debris of the debris, other properties are not as well preserved. Most deposits result from resedimentation of till and debris by sediment gravity flows, meltwater sheet and rill flow, slump, spall, and ice ablation. Depositional processes are interrelated in the process of backwasting of ice-cored slopes. Sediment flows are the primary process of resedimentation. Their physical characteristics, multiple mechanisms of flow and deposition, and characteristics of their deposits vight the water content of the flow mass. Deposits of each process are distinguished from one another by defaulted the of their deposition and other or the content of the flow mass. each process are distinguished from one another by detailed analysis of their internal organization, geometry and dimensions, and the presence of other internal and related external features

Genetic facies are defined by these characteristics

ULTRASONIC VELOCITY INVESTIGATIONS OF CRYSTAL ANISOTROPY IN DEEP ICE CORES FROM ANTARCTICA.

ANTARCTICA—LITTLE AMERICA STATION. Ice cores from Byrd Station and Little America. V have been used to test an ultrasonic technique for evaluating crystal anisotropy in the Antarctic Ice Sheet. P-wave velocities measured parallel and perpendicular to the vertical axes of cores from the 2164-m-thick ice sheet at Byrd Station have yielded iesults in excellent agreement with the observed c-axis fabric profile and with the in-situ. P-wave velocity profile measured parallel to the bore hole axis. Velocity differences in excess of 140 m/s for core samples from deeper than 1300 m attest to the strong single pole clustering of crystallographic c-axis about the vertical especially in the zone from 1300-1800 m. Such oriented structure is compatible only with strong horizontal shearing in the zone. The cristence in an ice sheet of widespread shearing several hundred meters above its bed raises serious questions as to the validity of current concepts of the flow of large ice masses that tend to gloss over originore crystal alignments of this magnitude. The ultrasonic technique has proven to be a fast and powerful tool for determining crystal fabrica in ces sheets. Results from Byrd Station and Lattle America. in ice sheets Results from Byrd Station and Little America V, together with fabric data from several other locations in East Antarctica suggest that crystal orientations within the Antarctic Ice Sheet tend to be characterized by either single or multi-pole clustering of c-axes about a vertical symmetry axis

WATER SUPPLY, DEFECTION, GROUND WA TER, WAVES MAGNETIC PROPERTIES. RADIO

This report discusses the application of several modern geo physical techniques to groundwater expioration in areas of permafrost. These methods utilize the principles of magnetic induction and radiowave surface impedance in the 10-to 400 kHz band, the techniques of impulse and side-looking radar in the 50- to 10 000 MHz band, and also some optical radar in the 50- to 10 000 MHz band, and also some optical techniques using imagery obtained from a satellite, all for detecting free water under an i.e cover in shallow, almost completely frozen lake basins, and thaw zones within lake beds, stream channels and in permafrost in general. The radar studies demonstrate the use of these techniques for determining depth of free water and ice cover thickness on lakes and rivers.

CR 79-16 CONSTRUCTION AND PERFORMANCE OF MEMBRANE ENCAPSULATED SOIL LAYERS IN ALASKA.

Smith, N. June 1979, 27p, ADA-073 531, 17 refs. 34-134

SOIL FREEZING, COLD WEATHER TESTS, FROST PROTECTION, SOIL WATER, WATER-PROOFING, FROST HEAVE

In 1973 two membrane encapsulated soil layer (MESL) test In 1973 two membrane encapsulated soil layer (5185), feet sections were constructed into existing gravel surfaced roads at Limendorf ALB and at Lt Wainwright in Anchorage and Lairbanks, Alaska respectivels. The Himendorf ALB MESL contains a suits clay soil and the Et Wainwright MISL contains a nonplastic silt. Both sections were constructed at soil moisture contents of approximately 2% to 3% below optimum for the CE-12 compactive effort. There were no indications of soil moisture migration during freezing in either test section, and at, r-thaw field California Bearing Ratio values were nearly equal to values measured before freezing. There is growing evidence of a slight increase in the overall soil moisture content in the Elmendorf AFB in the overall soil moisture content in the Elmendorf AFB MESL, p subly from moisture entering through the single layer polyethylene sidewalls which were not treated with asphalt emulsion. There is good evidence that the membrane of the same section might have received damage during a soil sampling operation which allowed localized moisture infiltration. A two-layer polyethylene membrane used in the Ft. Wainwright MESL is considered a more positive moisture barrier than the single sheet and a justifiable added cost for permanent construction.

CD 70-17 ROOF RESPONSE TO ICING CONDITIONS. Lane, J.W., et al, July 1979, 40p., ADA-074 477, 12 cefe

ROOFS. THERMAL CONDUCTIVITY, ICING, MELTING, SLOPE ORIENTATION.

MELTING, SLOPE ORIENTATION.

Six test roofs of two different slopes—16.3 deg and 39.8 deg, and three different roof coverings—asphalt shingles, cedar shingles, and corrugated aluminum sheeting, were constructed at USACRREL, Hanover, New Hampshire, and were instrumented with thermocouples, heat flow meters, and calibrated gutters the winters of 1971-72 and 1972-73. The degree of 1971 and 1972-73. It was found that eave using is a sensitive function of the slope, roof covering composition, and solar radiation. The effects of wind were not investigated, the slats were screened to remove all information corresponding to windspeeds over 8 km/h in order of increasing tendency to form tee dams on the eaves, the roofs were high-slope asphalt, high-slope cedar, and low-slope aluminium, low-slope asphalt, low-slope cedar, and low-slope aluminium. high-slope aluminum low slope aluminum

INSULATING AND LOAD-SUPPORTING PROPERTIES OF SULFUR FOAM FOR EXPEDIENT ROADS IN COLD REGIONS. Smith, N., et al, Sep. 1979, 21p., ADA-074 694, 6 refs.

ROADS, THERMAL INSULATION, CELLULAR MATERIALS, BEARING STRENGTH, FREEZE

THAW CYCLES.

Temperatures of the subgrade and of sulfur foam insulation test sections in an expedient road were monitored with thermocouples to document freezing and thawing conditions. Vehicular trafficking was conducted in a limited basis to determine the load supporting capabilities of the foam. The sulfur foam, placed directly under a prefabricated surface mat, was found to be unsuitable for use as an expedient thermal insulation and traffic load supporting material, primarily because of its low tensile strength and high brittleness. The insulating value of sulfur foam produced by the batch process in the field was about one-half that of extruded polystyrene, meaning double the thickness for equal protection against thaw.

CR 79.19 CR 79-19 CRITICAL VELOCITIES OF A FLOATING ICE PLATE SUBJECTED TO IN-PLANE FORCES AND A MOVING LOAD.

Kerr, A.D., Aug. 1979, 12p., ADA-075 455, 6 refs

FLOATING ICE, DYNAMIC LOADS, A SLOCK

The critical velocities of loads moving over floating ice plates have been determined by several authors. In all these analyses it was assumed that the in-plane force field in the ice cover is zero. However, due to constrainat thermal strains, in-plane forces do occur in the field. The purpose of the present paper is to determine their effect upon the critical velocities of the moving loads. It is shown that a uniform compression force field reduces the critical velocity, whereas a tension force has the opposite

VOLUMETRIC CONSTITUTIVE LAW FOR SNOW SUBJECTED TO LARGE STRAINS AND STRAIN RATES.

Brown, R.L., Aug 1979, 13p., ADA-075 474, 10 rcfs. 34-913

SNOW DEFORMATION, SNOW COMPRESSION, VOLUME, STRAINS, STRAIN TESTS DYNAMIC LOADS, TRACKED VEHICLES

A volumetric constitutive equation was developed to character rize the behavior of snow subjected to large compressive volumetric deformations. By treating the material as a suspension of air soids in a matrix material of polycrystalline. ice, a rate-dependent volumetric constitutive law was formulatce, a rate-opendent volumetric constitutive law was formulated and found to accurately predict material response to pressure loads for a wide range of load rates. Comparison of the theory with shock wave data was not considered in this paper, although the constitutive law appears to be valid for such load vituations. One application to oversnow

mobility of tracked vehicles was made. In this case, power requirements due to snow compaction were calculated parametrically in terms of vehicle speed, tra k loading, and sno v

CR 79-21 TOWING SHIPS THROUGH ICE-CLOGGED CHANNELS BY WARPING AND KEDGING. Mellor, M., Sep. 1979, 21p., ADA-077 801, 6 refs. 34-1380

CHANNELS (WATERWAYS), ICE COVER, ICE PRESSURE, SHIPS, ANCHORS.

CHANNELS (WATERWAYS), ICE COVER, ICE PRESSURE, SHIPS, ANCHORS.

The report studies the question of whether Great Lakes freighters could move effectively through ice-clogged channels with the aid of tows provided by warping or kedging systems. Ten operational concepts are outlined, and their advantages and disadvantages are noted. The crushing resistance of floating brash ice is then analyzed. The neutral, retive and passive state, of stress for laterally confined brash ice are considered, and the resistance to horizontal turnisting by a smooth vertical wall is calculated for cohesion between the ice fragments. The thickening of the ice cover in the vicinity of a "pusher" and the formation of pressure ridges are analyzed in order to estimate the amount of pile-up that can occur against a ship hull. The analysis then moves on to consideration of ship resistance at the bow, tangential friction at the bow, and the hull friction aft of the bow section. Comparisons are made between thrust from the ship's screws and the calculated ice resistance. The next section of the report estimates the force requirements for a waiping or ledging system in terms of thrust augmentation for existing vessels. Tow cable requirements are given, and estimates are made for cable anchors and for anchorage of underwater structures. The force and power requirements for winches and windhawas are given, the practical problems involved in the pickup or transfer of cables are mentioned, and the report concludes with a brief appraisal. The conclusion is that a simple warping tug system is appropriate for a full-scale experiment, a chain ferry with auxiliary barge seems attractive for an operational system, and a chain ferry with auxiliary barge seems attractive for an operational system, and a chain ferry with auxiliary barge seems attractive for an operational system, and a chain ferry with auxiliary barge seems attractive.

ELECTRICAL PROPERTIES. ELECTRIC CHARGE, DISLOCATIONS (MATERIALS), RAY ANALYSIS, ICE CRYSTAL STRUCTURE.

The motion of dislocations in single crystal ice under an electi. fit.d was observed by using X-ray topographic methods Electric charge density or, these dislocations was deduced from the amplitude and length of the dislocation segment under the known AC electrical field. In finear charge density, considerable variation is possible, depending on the effective field acting on the dislocation lines.

CR 79-26 LAKE CHAMPLAIN ICE FORMATION AND ICE FREE DATES AND PREDICTIONS FROM METEOROLOGICAL INDICATORS.

Bates, R E, et al, Nov. 1979, 21p., ADA-079 640, 11

Brown, M.-L. 34-1745

LAKE ICE, ICE FORMATION, ICE BREAKUP, METEOROLOGICAL DATA, PERIODIC VARIA-

TIONS
A 19-yr record of the annual closing and opening rates of operation of the Lake Champlain ferry at Grand Isle, Vermont, which are controlled by the lake's nee cover, was made available to CRREL. These navigation records accurately approximated the freeze-over and breakup dates for the ferry crossing area between Gordon Landing. Vermont, and Cumberland Head, New York. When compared statistically with water temperature and climatological data for the same years at nearby Lake Champlain locations, the dates allowed accurate predictions of nee formation. From nearby air temperature records, cumulative freezing degreeday (C) curves were plotted for each year of record, and nee formation dates and standard deviations were predicted with considerable accuracy. Several methods of predicting ice formation on Lake Champlain were attempted. The most accurate approach used a combination of water temperatures and freezing degree-days. The influence of wind speed on ice cover formation and prediction are also discussed in the report.

ANALYSIS OF PLASTIC SHOCK WAVES IN SNOW.

Brown, R.L., 1979, 14p., ADA-080 051, 12 refs.

WAVE PROPAGATION, SNOW DEFORMA-TION, SHOCK WAVES, LOADS (FORCES), ANALYSIS (MATHEMATICS).

ANALYSIS (MATHEMATICS).

At analytical study of the propagation of shock waves in snow was carried out to evaluate the response of medium density snow to high rates of loading. One solution was developed for steady shock waves, this resulted in calculation of pressure jump, density jump and stress wave speed. Correlation with available experimental data was fecund to be good. Nonsteady shock waves were also considered in order to evaluate wave attenuation rates in snow. Very few data were available to compare with the analytical results, so no definite conclusions on the part of the study could be made. The results show, however, that shock waves that produce plastic deformation attenuate at extremely high rates and that differences in pressure between two waves are quickly eliminated within a short distance. Calculations were also made to evaluate the effect of wave frequency are quickly eliminated within a short distance Calculations were also made to evaluate the effect of wave frequency on attenuation rates. The results show that, for plastic waves, frequency is not a predominant factor for determining attenuation rates (Auth.)

IMPROVED ENZYME KINETIC MODEL FOR NITRIFICATION IN SOILS AMENDED WITH AMMONIUM. 1. LITERATURE REVIEW

Leggett, D.C., et al, Jan 1980, 20p, ADA-082 303, Refs. p.18-20. Iskandar, I.K.

35-2583

WASTE TREATMENT, WATER TREATMENT, CHEMISTRY, SOIL MICROBIOLOGY, GROWTH.

Previous research indicates that intrification in pure cultures can be represented by Michaelis-Menten kinetics. However, the effects of temperature and especially pH have not been treated systematically in any of the previous reviews of the subject. The work reported here is an attempt to synthesize reported temperature and pH effects on intrification and nitrifier growth rates. In addition we attempt to extend the principles of microbial kinetics to soils. Our work indicates that pH effects can be interpreted mechanistically as inhibitions by hydrogen and hydroxyl ions, initious acid, and ammonia. These are incorporated into the Michaelis-Menten expressions. It is also our observation that ammonium oxidizers in natural habitats are chalacterized by lower Michaelis constants than pure cultures. This is significant particularly in terms of their prowth and activity in acid soils. Alternatively, we speculate that provincestion. Previous research indicates that nitrification in pure cultures of ammonium oxidizers in acid soils is due to spati-heterogeneity of "pH" at the microsite level

The primary objectives of this study were to 1) prepare
a map from Landsat imagery of the Upper Sustina River
Basin drainage network, lakes, glaciers and snowfields, 2)
identify possible faults and lineaments within the upper basin
and within a 100-km radius of the proposed Devil Canyon
and Watai... dani sites as observed on Landsat imagery,
and 3) prepare a Landsat-derived map showing the distribution
of surficial geologic materials and poorly drained areas. The
EROS Digital Image Enhancement System (EDIES) provided
computer-enhanced images of Landsat-1—scene 5470-19560.
The EDIES frive color composite of this scene was used
as the base for mapping diamage network, lakes, glaciers
and snowfields, six surficial geologic materials units and
poorly drained areas. Some langle-band and other color
composites of Landsat images were used during interpretation
All the above maps were prepared by photointerpretation
of Landsat images without using computer analysis, aerial
photographs, field data, or published reports

*Y, TRAFFICABILITY
Payements containing soft asphalt cement have been shown in the past to be less succeptible to low-temperature contractio-cracking, but more susceptible to traffic load-associated distress in ware weaths. This resease comprised laboratory testing to determine the properties of asphalt-aggregate mixtures containing three grades of asphalt-aggregate mixtures containing three grades of asphalt cements, and analyses to project the performance of payements containing each of the asphalts, in resisting thermally induced distress and traffic associated distress. From the results it is concluded that only the softest asphalt cement cested (AC 25) would perform satisfactorily in a cold clinic to 25. The moderately soft (AC 5) and moderately hard (so 20) asphalt cements showed little susceptibility to thermal care long in a moderate and a warm climitation respectively. The AC 25 and AC 5 asphalts are not recommended for use in warm climates however, owing to increased susceptibility to rutting under traffic. increased susceptibility to rutting under traffic

MAXIMUM THICKNESS AND SUBSEQUENT DECAY OF LAKE, RIVER AND FAST SEA ICE IN CANADA AND ALASKA.

Bilello, M.A., Feb 1980, 160p., ADA-084 488, 57

ICE COVER THICKNESS, ICE MELTING, ICE DETERIORATION, LAKE ICE, RIVER ICE, SEA ICE, FAST ICE, AIR TEMPERATURE, ICE FORE CASTING

Weekly measurements of the thickness of lake, river and fast sea ice made over a period of 10 to 15 years at 66 locations in Canada and Alaska are analyzed, and the portion locations in Canada and Alaska are analyzed, and the portion of the data relating to maximum ice thickness and decay (i.e. the decrease in ice thickness) is examined. Ice thickness surves revealed individual patterns of ice decay, and comparisons between locations disclosed major contrasts in the amount of ice are ation and the times of maximum ice and ice cleara. Although many factors affect the ice decay process, this study investigates in detail the effect of thawing temperatures. Concurrent measurements of the air temperature at each location, and et a possible analyze the relationship. temperatures

Concurrent measurements of the air temperature at each location made it possible it analyze the relationship between accumulated thawing degree flays (ATDD) and ice cover decay.

Other factors affecting ice ablation and breakup, such as snow-ice formation, snow cover depth, solar radiation and wind are also discussed

COMPUTERIZED SIMULATION, LABORATORY TECHNIQUES, FORECASTING.

COMPUTERIZED SIMULATION, LABORATO-RY TECHNIQUES, FORECASTING.

A mathematical model of coupled heat and moisture flow in soils has been developed. The model includes algorithms to phase change of soil moisture and frost heave and permits several types of boundary and initial conditions. The finite element method of weighted residuals (Galerkin procedure) was chosen to simulate the spatial regime, and the Ciank-Nicholson method was used for the time domain portion of the model. To fac.litate evaluation of the model, the heat and moisture fluxes were extentially decoupled; moisture flux was then simulated accurately, as were heat flux and frost heave in a laboratory test. Companson of the simulated and experimental data illustrates the importance of unsaturated hydraulic conductivity. It is one parameter which is difficult to measure and for which only a few laboratory test results are available. Therefore, cuisaturated hydraulic conductivities calculated in the computer mod... may be a significant source of error in calculations of frost heave. The algorithm incorporating effects of surcharge and overburden was inconclusively evaluated. Time-dependent frost penetration and frost heave in laboratory specimens were closely simulated with the model. After 10 days of simulation, the computed frost heave was about 23 cm vs 20 cm and 28 cm in two tests. Frost penetration was computed as 15 cm and was measured at 120 cm and 122 cm in the two laboratory samples after 10 days.

CR 80-11 ROOF LEAKS IN COLD REGIONS: SCHOOL AT

Johnson, P.R.

ROOFS, LEAKAGE, BUILDINGS, MELTWATER, SNOW ACCUMULATION, CONDENSATION, SUBPOLAR REGIONS.

SUBPOLAR REGIONS.
Four types of roof leaks occurred at a new school building in Cheval. Alas. a 1) blowing snow entered the roof through eave vent and then melted, 2) slish and ice in roof valleys caused meliwate, to overflow the valley flashing and run into the bairing, 3) water entered at a roof/wall intersection and 4) in warva areas water entered through gaps in the stoping ply 1000 deck. Sealing the eave vents made it impossible blowing snow to enter the roof at the caves eliminated the valley teing problem Missing flashing was responsible for the roof-wall intersection leaks. The absence of a vapor barrier in the roof was the cause of many leaks. It was recommended that the roof be repaired from the exterior by removing componen elements down to the plywood deck, installing an adhered continuous vapor barrier and reassembling the roof. An alternative roof cladding of compiration shingles was discussed as was conversion to a "cold roof." The roof was repaired and midfied following recommendations, and problems appear to have been solved.

SIMPLIFIED MODEL FOR PREDICTION OF NITROGEN BEHAVIOR IN LAND TREAT-MENT OF WASTEWATER.

WASTE TREATMENT, WATER TREATMENT.

WASTE TREATMENT, WATER TREATMENT, NUTRIENT CYCLE, SOIL CHEMISTRY
A simplified model for simulation of nitrogen transformations and transportation in land treatment of wastewater is presented. The purpose of the model is to predict the behavior of NH4-N and NO3-N in the soil profile in land treatment systems. The program is based on the solution of the transient soil water flow equation simultaneously with the equations describing the transformation, transport, and plant uptake of nitrogen in the soil. The program is valid.

for uniform as well as multilayered soil profiles and can for uniform as well as multilayered soil profiles and can be adapted to incorporate various nitrogen transformation mechanisms and boundary conditions. The model can be used as a tool to predict the fate of nitrogen in land treatment systems. Model sensitivity to changes in the rate of nitrification, ammonium ion exchange, and ate of plant uptake of nitrogen is also described. Description of the computer program, the program listing, and an example of input data and a two-week computer simulation of output data are presented.

CR 90-13 FRACTURE BEHAVIOR OF ICE IN CHARPY IMPACT TESTING.

Sabourin, L

ICE CRACKS, FRACTURING, IMPACT TESTS TEMPER/ JURE EFFECTS, DOPED ICE, IC COMPOSITION, ICE CRYSTAL STRUCTURE.

COMPOSITION, ICE CRYSTAL STRUCTURE. Specimens prepared from various types of ice without introducing excessive defects were tested at temperatures ranging from -2 to -190C. These tests indicated slightly higher Chaipy values at lower temperatures and in more highly dispersed material concentrations. Three modes of fracture occurred during testing. Depending on the temperature and the material composition, either of the first two modes rormal fracture or multiple fracture, will appear and will small a normal frequency distribution of Charpy values in each type of ice. The third mode, fracture from both ends, which requently occurred in the (NH4F) doped ice, gave Charpy values two to five times higher than the mean value for normal fracture. It can, therefore, be concluded that certain types of doping can alter the mode of fracture, the which drastic modifications of impact resistance may be possible.

CR 80-14 CR 80-14 GEOBOTANICAL ATLAS OF THE PRUDHOE BAY REGION, ALASKA. Walker, D.A., et al, June 1980, 69p., Refs. p.45-47. Everett, K.R., Webber, P.J., Brown, J.

UNITED STATES-ALASKA-JUDHOE BAY

. JUDHOE BAY

This atlas illustrates the interrelationships among the landtorms, soils and vegetation of a portion of the Arctic Coastal

Plain of Alaska. The Prudhoe Bay region is dominated
by an alkaline peaty coastal tundra, a type that has not
been intensively studied. Forty-two vegetation communities, thirteen maior landicorms, end eight soil types are desenbed. Several of the plant communities and one soil,
the Pergelic Crobotoil, have not been described previously.

The vegetation is discussed with respect to three important
gradients temperature, soil pH and soil moisture. Other
aspects of the Prudhoe Bay environment, including geology,
permafforst, and winter and summer climate, are discussed
and illustrated. Also included are historical descriptions permatrost, and winter and summer climate, are discussed and illustrated. Also included are historical descriptions of the development of the oilfield and of selected scientific investigations in the Alaskan Arctic. Master maps present the landforms, soils and vegetation of a 145-sq km portion of the oilfield road network at a scale of 1 12,000. Derived geobotanical special purpose maps, useful for land-use planning and management of the ecosystem, are expanned and several examples are shown for a 3-6 so km portion of the oilfield

CONSTRAINTS ON MEASURING TIME BUILDING R-VALUES. Flanders, S.N., June 1980, 30p., ADA-089 712 18

SEAICE, ANISOTROPY, ICE STRENGTH, ELEC-TROMAGNETIC PROPERTIES, ICE CRYSTAL STRUCTURE. BRINES. OCEAN CURRENTS. RADIO ECHO SOUNDINGS.

RADIO ECHO SOUNDINGS.

Results of impulse radar studies of sea ice give support to the concept of a sea ice model in which the ice bottom is composed of an array of lossy parallel plate waveguides. The fundamental relation between the average bulk brine volume of sea ice and its electrical and strength properties discussed as is the remote detection of under-ice currer alignment. It was found that 1) the average effective balk dielectric constant is dependent upon the average bulk brine volume of the sea ice, 2) sea ice anisotropy, arising from a bottom structure of crystal platelets with a preferred casis horizontal alignment, can be detected by radio echo from a bottom structure or crystal patients with a preterror castic horizontal alignment, can be detected by radio echo sounding measurements made not only on the ice surface but also from an airborne platform; 3) the effective coefficient of reflection from the sea ice bottom decreases with increasing average effective bulk dielectric constant of the ice, decreases with increasing bulk brine volume, and is typically one to two orders of magnitude lower than the coefficient of reflection from the ice, surface; and 4.) the losses in sea ice increases from the ice surface; and 4) the losses in sea ice increase with increasing average bulk brine volume.

ANISOTROPY, SEA ICE, ELECTROMAGNETIC PROPERTIES, BRINES, DIELECTRIC PROPERTIES, MATHEMATICAL MODELS, ICE CRYSTAL STRUCTURE, REFLECTIVITY, RADAR **ECHOES**

ECHOES.

The contribution of brine layers to observed reflective anisotropy of sea ice at 100 MHz is quantitatively assessed. The sea ice is considered to be a stratified, inhomogeneous, anisotropic dielectric consisting of pure ice containing ordered arrays "conducting inclusions (brine layers). Below the transition some, the ice is assumed to have constant azimuthal casts on ation within the horizontal plane, so that the orientation some layers is uniform. The brine layers are also assumed: 5 to become increasingly well-defined with depth, since adjacent brine inclusions tend to fuse together with increasing temperature. A theoretical explanation for observed reflective anisotropy is proposed in terms of anisotropic electric flux penetration into the brine layers. Fenetration anisotropy and brine layer geometry are linked to anisotropy in the complex dielectric constant of sea ice. In order to illustrate the above effects we present a numerical method of approximating the reflected power of a plane wave pulse incident in a slab of sea ice. Mixture dielectric constants, i...lustated for two polarizations of the incident wave, are used to calculate power reflection coefficients for the two polarizations.

MEASUREMENT OF THE SHEAR STRESS ON THE UNDERSIDE OF SIMULATED ICE COV-RS.

IZE MECHANICS, SHEAR STRESS, HYDRAU-LICS, SUBGLACIAL OBSERVATIONS, SUR-FACE ROUGHNESS, WATER, VELOCITY, EX PERIMENTATION, MODELS.

PERIMENTATION, MODELS.
The fluid shear stress applied to the underside of a simulated floating ice cover was measured in a laboratory flume. The measured values were compared with values of the shear stress computed from the von Karnan-Prodit velocity distribution fitted to the velocity profiles managed velocity that the cover. For the loner velocity runs (about 6079 m/s) the measured and computed values of the shear stress were in close agreement. At the high velocity flows (about 0.138 m/s) the measured values were roughly one-half those calculated from the velocity distribution. As the underside of the cover became increasingly rougher, the position of maximum velocity moved closer to the bottom of the channel, It was shown that the Darcy friction condition, ent is exponentially related to a normalized ice cover thickness, which suggests that it is measure of the roughness of a fragmented ice cover.

ICE LOADS, RIVER ICE. BRIDGES, MEASURING INSTRUMENTS, LOADS (FORCES).

ING INSTRUMENTS, LOADS (FORCES).

Two new types of load cells for attachment to bridge piers and direct measurement of ice for es were developed and tested with one type ben,g installed on a pier of the Yukon River Bridge northwest of Fairbanks. Alaska Both types of load cells used beams supported by base plates and carried nose plates that were loaded by the ice. The loads were imposed at the beams at locations differing from the support reactions so that the loads developed moments in the beams. By instrumenting them with strain gauges, the loads could be measured. Details of the design of the load cells, the means of calculating the loads and experience obtained with load cells are discussed.

BLOCK MOTION FROM DEPONATIONS OF BURIED NEAR-SURFACE EXPLOSIVE AR-RAYS.

Blouin, S.E., Dec. 1980, 62p. ADA-095 492, 31 refs

35-1999 ROCK MECHANICS, EXPLOSION EFFECTS, EXPLOSIVES, SUBSURFACE STRUCTURES, SOIL MECHANICS.

SOIL MECHANICS.

A vital concert to the survivability of hardened underground structures in rock is the relative displacement induced along geologic discontinuities by nearby caplisions. Such displacement, commonly termed block motion, can occur along faults, joints, bedding planes and other structural weaknesses in rock. This report documents all occurrences of block motion observed during the development of DIHEST, a series of shallow-buried high exposive experiments designed to simulate the direct induced ground motions from a nuclear surface burst. Instances of block motion are described,

along with pertinent details of the explosive arrays, geology and ground motion fields. The influence of these and other factors on the direction and magnitude of block motion is discussed.

PHASE CHANGE AROUND A CIRCULAR PIPE. Lunardini, V.J., Dec. 1980, 18p., ADA-094 600, 12

35-1894

35-1894
PIPES (TUBES), HEAT TRANSFER, PERMA-FROST THERMAL PROPERTIES, STEFAN PROBLEM, PHASE TRANSFORMATIONS, FROZEN GROUND STRENGTH, THERMAL DIFFUSION, FREEZE THAW CYCLES, ANAL-YSIS (MATHEMATICS).

YSIS (MATHEMATICS).

No general, analytical solution exists for phase change around a cylinder, thus, approximate methods have been evaluated. The heat balance integral technique applied to the cylinder gave excellent results when compared to published numerical solutions. Graphical solutions are given for phase change about a cylinder for ranges of the Stefan number, superheat parameter, and property value ratios for typical soils. An approximate, general solution has been derived which is reasonably accurate and can be used for any values of the above-mentioned parameters. The effective thermal differenties method has been shown to be useful for practical forms. above-mentioned parameters. The effective thermal dif-fusivity method has been shown to be useful for practical problems of phase change

FIELD COOLING RATES OF ASPHALT CON-CRETE OVERLAYS AT LOW TEMPERATURES. Eaton, R A., et al. Dec 1980, 11p. ADA-095 489, 7

Berg, R.L. 35-2002

TEMPERATURE EFFECTS, BITUMINOUS CON-CRETES, COOLING RATE, LOW TEMPERA-TURE TESTS, ROADS, PAVEMENTS, COMPAC-

Six overlay test sections were placed on an existing test road in Hanover New Hampshire, to gain experience in

compaction of asphalt pavements at rolling temperatures as low as 150 F The asphalt cement and aggregate used had mix characteristics similar to those of the mix expected to be used for a proposed overlay project at Thule Air Base, Greenland. Results of the overlay tests showed to be used for a proposed overlay project at Thule Air Base, Greenland. Results of the overlay tests showed that computer-modeled cooling curves can be accurate predictors of the actual asphalt overlay cooling with time. In Addition, the effects of temperature upon compaction were determined and it was found that nuclear gauges, when used and calibrated properly, successfully monitored mix density changes during compaction

HYPERBOLIC REFLECTIONS ON BEAUFORT SEA SEISMIC RECORDS

Neave, K.G., et al. Mar. 1981, 16p., ADA-099 172, 8 refs.

Sellmann, P.V., Delaney, A.J

36-31R

BOTTOM SEDIMENT, SEISMIC REFLECTION, OCEAN BOTTOM, ICE CONDITIONS, SEA ICE. REAUFORT SEA.

Many hyperbolic reflections have been observed on marine Many hyperbolic reflections have been observed on manne seismic records obtained during oil exploration in the Beaufort Sea, and on USGS seismic sub-bottom profiles from the Frudhoe Bay vicinity. A hyperbolic projection system was designed to rapidly measure seismic velocities from the curves on the records. The velocities observed were approximately the velocity of sound in water. The hyperbolic signals also showed dispersion properties similar to acoustic normal modes in shallow water. These observations indirect that the signals responsible for the hyperbolic reflections propagate as normal modes within the layer, with very limited penetration of the seabed. Determinations of the dominant frequency of these seanls indicate that the neglection into penetration of the scabed Determinations of the dominant frequency of these signals indicate that the penetration into the scabed has a characteristic attenuation depth (skin depth) of about 1.5 m for the sub-bottom profiles and 12 m for the marine records. If therefore appears that some hyperbolic reflections may be generated by variations in materials that occur near the scabed There is some evidence of incently of the anomalies, possibly related to sediment-filled or open ice gouges, or other changes in material properties at shallow depths.

HYDRAULIC MODEL STUDY OF A WATER IN-TAKE UNDER FRAZIL ICE CONDITIONS. Tantillo, T.J., Mar. 1981, 11p., ADA-099 171, 8 refs 36-319

WATER INTAKES, ICE CONDITIONS, FRAZILICE, HYDRAULIC STRUCTURES, ICE PREVEN-TION, PROTECTION, MODELS, BUOYANCY

TION, PROTECTION, MODELS, BUOYANCY A 1 24 scale hydraulic model study of a water intake under frazil ice conditions is presented. The intake, liceated 9 m below the surface of the St. Lawrence River in Massena New York, has a throughflow of 0 14 cut m s. The model study, conducted in the refrigerated flume facility of the U.S. Army. Cold Regions Research and Engineering Laboratory, investigated methods of minimizing the frazil ice blockage on the intake. Two protective structures were modeled

and the relative benefits of each are presented — The addition all cross-sectional area provided by the protective structures lowered the vertical velocity component of the intake water to 0.0027 m/s — At this velocity the buoyant force acting on the frazil ice particle is larger than the downward drag force, causing the particle particle to rise. — The results demonstrate that under certain low flow conditions a protective structure—can minimize frazil ice blockage—problems

CR 81-04 MOVEMENT STUDY OF THE TRANS-ALASKA PIPELINE AT SELECTED SITES

Ueda, H.T., et al, Apr. 1981, 32p., ADA-101 605, 3

Garfield, D.E., Haynes, F.D. 36-320

PIPELINES, MECHANICAL PROPERTIES, STA BILITY, PIPELINE SUPPORTS, ANCHORS, UNITED STATES—ALASKA.

UNITED STATES—ALASKA.

Eight sites along the trans-Alaska pipeline from the Denali Fault to Fairbanks were selected for pipeline and pipeline support movement studies. Four measurement surveys were conducted, starting before oil pumping operations began up to September 2, 1978, to determine the lateral and longitudinal pipe movement due to the thermal expansion of elevated sections of the pipeline, the tilt of the vertical support members (VSM's), and the changes in relative elevation of the support crossbeams. A maximum lateral and longitudinal motion of the pipe of 13 3/4 in and 2 3/16 in respectively were measured up to September 1978. Tilt data for 180 VSM's showed intile change over a one-year period, with only 5 VSM's tilting more than 0.5 deg. Relative elevation measurements showed insignificant changes for two sites compared over a one-year period. Comparisons of our data with as-built elevations at 8 sites shows a few large differences that cannot be readily explained. In general the pipeline and its supports, at least at the sites studied, show minimal movement and activity.

CR \$1-05 VIBRATIONS CAUSED BY SHIP TRAFFIC ON AN ICE-COVERED WATERWAY.

Haynes, F.D., et al, Apr. 1981, 27p., ADA-101 541, 11

Maattanen, M.

36-321 SHIPS, VIBRATION, ICE BREAKING, ICE COV-ER. FROZEN GROUND, SEISMOLOGY.

SHIPS, VIBRATION, ICE BREARING, ICE COVER, FROZEN GROUND, SEISMOLOGY.

Vibrations have been felt on shore along the St. Marys River in Michigan during the passage of ships through ice vibration measurements were made on a ship, on the ice, on the shore, and on buildings along the shore. Vibration levels in 1979 were about an order of magnitude lower than levels that would cause damage to building walls. Two factors, however, could have reduced the vibration levels in 1979 a lack of ice jams and a record high snow cover which prevented the soil from freezing. Vibration levels with an ice cover are about four times those without an ice cover are about four times those without an ice cover lectreaking and opening the channel can reduce vibration levels by about 50% for a ship following closely behind another ship. The dominant frequencies measured on shore were associated with propeller excitation. The dominant frequencies and magnitudes measured on the bow of a ship are an order of magnitude higher than those on the shore and are related to icebreaking by the bow Vibration magnitudes are dependent upon the velocity of the ship, the erroy expended by the ship, the cross-sectional area of the ship, weather, conditions of the ice and soil, and site-specific conditions. Further studies are needed to determine the effects of these factors and to determine the mode of energy transmission. the mode of energy transmission

INVESTIGATION OF THE ACOUSTIC EMIS-SION AND DEFORMATION RESPONSE OF FI-NITE ICE PLATES.

Chaplin, M. St. Lawrence, W.F.

ICE ACOUSTICS. FRACTURING, ICE LOADS, PLATES. ICE DEFORMATION, ICE CRACKS. ANALYSIS (MATHEMATICS)

ANALYSIS (MATTER-MATTER)

A procedure is described for monitoring the microfracturing activity in ice plates subjected to constant loads. Sample time records of freshwater ice plate deflections as well as corresponding total acoustic emission activities are presented. The linear clastic, as well as viscoelastic, response for a simply supported rectangular ice plate is given. Suggested future work using to above procedure is discussed.

CR \$1.07 HYDRAULIC CHARACTERISTICS OF THE DEER CREEK LAKE LAND TREATMENT SITE DURING WASTEWATER APPLICATION.

Abele, G., et al. Apr. 1981, 37p., 3 refs. McKim, H.L., Caswell, D.M., Brockett, B.E. 36-390

WATER, WASTE DISPOSAL. TREATMENT, HYDRAULICS, DRAINAGE, IR-RIGATION, SEEPAGE, LAND RECLAMATION During the summer of 1979, wastewater was applied 10 times to the Deer Creek Lake, Ohio land treatment site Wastewater fistribution on the ground during spray application is not uniform some locations receive less than 70% and

others more than 130°, of the mean amount applied The saturated infiltration rate ranges from moderately slow (0.6 cm/hr after 1 hr) to slow (0.3 cm/hr after 12 hours) The flow rate increases approximately as the cube under-drain flow rate increases approximately as the cube of time until 1 hour after the end of application and then decreases as the reciprocal of time squared. The rate and amount of drainage increases with an increase in the initial soil water content and can be predicted from soil tension measurements. It was possible to calculate the mass water budget at the end of a typical application to within 88% of the actual water applied. under-drain

CR 81-08 SEASONAL GROWTH AND UPTAKE OF NU-TRIENTS BY ORCHARDGRASS IRRIGATED WITH WASTEWATER.

Palazzo, A J., et al, May 1981, 19p. ADA-101 613, 33

refs. Graham, J.M.

GRASSES, NUTRIENT CYCLE, GROWTH, WASTE DISPOSAL, WATER TREATMENT, IR-RIGATION, LAND RECLAMATION, SEASON-AL VARIATIONS.

AL VARIATIONS.

A 2-year field study determined the seasonal growth and nutrient accumulation of a forage grass receiving 7.5 cm/wk of primary treated domestic wastewater. The average N and P concentrations in the wastewater were 31.5 and 6.1 mg/l respectively. An established sward of Pennlate orchardgrass (Dactylis glomerata L.) was managed on an annual three cutting system. Grass samples were periodically taken to determine plant dry matter accumulation and uptake of N, P and K. Changes in nutrient uptake within a harvest period were related to both changes in dry matter accumulation and plant nutrient concentration. For maximum yields and nutrient removal, it is recommended that accumulation and plant nutrient concentration For maximum yields and nutrient removal, it is recommended that orchardgrass be initially harvested at the early heading stage of growth in the spring Subsequent harvests should be performed at 5- to 6-week intervals Average daily dry matter, N and P accumulation was greatest during the first harvest period (May in Hanover, N H) This would be the most appropriate time to increase the application rate, thus treatment excess wastewater stored during the most the most appropriate time to increase the application rate, thus treating excess wastewater stored during the winter. Estimates of monthly plant removal for N and P are presented as a guide in designing land treatment systems according to the procedures given in the EPA/Corps Land Treatment Design Manual

CR 81-09 ON THE BUCKLING FORCE OF FLOATING ICE

Kerr, A.D., June 1981, 7p., ADA-103 733, 12 refs.

LOADS, PLATES, FLOATING ICE, ICE VER STRENGTH, DYNAMIC LOADS, COVER COVER STRENGTH, DY MATHEMATICAL MODELS

The calculation of the largest horizontal force a relatively thin floating ice plate may exert on a structure requires the knowledge of the buckling load for this floating plate in the published iterature on the stability of continuously In the published literature on the stability of continuously supported beams and plates, it is usually assumed that this buckling force corresponds to the lowest bifurcation force p(cr). However, recent studies indicate that, generally, this is not the case, and this report clarifies the situation for floating ice plates. This problem is first studied on a simple model that exhibits the buckling mechanism of a floating ice plate but is amenable to an exact nonlinear analysis. This study, shows that, depending on the ratio of the rigidities of the "fiquid" and "plate", the post-buckling branch may rise or drop away from the bifurcation point

CR 81-10
REVIEW OF THERMAL PROPERTIES OF SNOW, ICE AND SEA ICE.

Yen, Y.-C., June 1981, 27p, ADA-103 734, Refs. p 25-27. 36-393

ICE THERMAL PROPERTIES, SEA ICE, SNOW DENSITY, SNOW THERMAL PROPERTIES, ICE DENSITY, THERMAL PROPERTIES, COMPRES-SIVE PROPERTIES, THERMAL EXPANSION.

This treatise thoroughly reviews the subjects of density, thermal expansion and compressibility of ice, snow density change attributed to destructive, constructive and melt metamorphism. and the physics of regulation and the effects on penetration rate of both the thermal properties of the wire and stress level. Heat capacity latent heat of fusion and thermal conductivity of ice and snow over a wide range of temperatures. conductivity of ice and snow over a wide range of temperatures were analyzed with regression techniques. In the case of snow, the effect of density was also evaluated. The contribution of sapor diffusion to heat transfer through snow under both natural and forced convective conditions was assessed. Expressions representing specific and latent heat of sea ice in terms of sea ice salinity and temperature were given. Theoretical models were given that can predict the thermal conductivities of fresh bubbis ice and sea ice in terms of salinity, temperature and fractional air content. The salinity is a salinity to the conductivities of the substitutional air content.

CR 81-11 PREDICTION OF EXPLOSIVELY DRIVEN RELATIVE DISPLACEMENTS IN ROCKS.

Bloum, S.E., June 1981, 23p., ADA-101, 314, 15 refs 36-394 ROCK MECHANICS, EXPLOSION EFFECTS,

NUCLEAR EXPLOSIONS, SOIL MECHANICS, FORECASTING

Relative displacement data from high explosive, shallow-buried bursts in rock are combined with relative displacement data from the contained nuclear explosion MIGHTY EPIC data from the contained nuclear explosion MiOri FFE.
Analysis of these data yields a preliminary, semi-empirical
technique for predicting the location, direction sed magnitude
of relative displacements in rock from contained explosions.
This technique is used to make relative displacement predictions for the DIABLO HAWK nuclear blast.

REVEGETATION AND SELECTED TERRAIN DISTURBANCES ALONG THE TRANS-ALASKA PIPELINE, 1975-1978.

Johnson, A.J., June 1981, 115p., ADA-138 426, 41

38.4413

REVEGETATION, SOIL EROSION, GRASSES, PIPELINES, ENV ENVIRONMENTAL IMPACT,

FOLAR REGIONS.

Revegetation techniques along the trans-Alaska pipeline as employed by Alyeska Pipeline Service Company during the 1975-1978 summers were observed. Objectives included determining the success of treatments, identifying problem areas, and noticing long-term implications. Observations and photographs at 60 sites located along the trans-Alaska pipeline indicated frequent occurrence of successful revegetation as well as frequent problems, such as erosion, slowly tion as well as frequent problems, such as erosion, slope instability, poor scheduling of seed application, occurrence of weed species, failure to optimally reuse topsoil and fine-grained soil, and low rates of native species reinvasion grained soil, and low rates of native species reinvasion Alyeska's visual impact engineering was observed to be very successful as shown by high first-season survival. However, a related program for establishing willow cuttings was unsuccessful in 1977 but appeared very promising in 1978 largely due to improved management and more favorable growing conditions. Terrain disturbances due to the construction of the fuel gas line, snowpads, and oil spills were examined to identify and describe related environmental impacts on natural vegetation. Proper construction and use of snowpads minimized the extent and severity of disturbance. Crude oil spills, although damaging to vegetation, did not cause total kill of vegetation, and certain types of spills may have only short-term effects. Results of restoration research by CRREL along the trans-Alaska pipeline are discussed.

CR \$1-13 VHF ELECTRICAL PROPERTIES OF FROZEN GROUND NEAR POINT BARROW, ALASKA. Arcone, S. A., et al, June 1981, 18p., ADA-103 735, 32

Delaney, A.J.

36-395 PERMAFROST PHYSICS, DIELECTRIC PROP-ERTIES, RADIO WAVES, FROZEN GROUND PHYSICS, SOIL COMPOSITION, WATER CON-TENT, ORGANIC SOILS.

TENT, ORGANIC SOILS.
Electrical properties of frozen ground were measured using radio frequency interferometry (RFI) in the very high frequency (VHF) radiowave band leerich organic silts and sands and gravels of variable see content were investigated during early April of both 1979 and 1980. Frequencies between 10 and 150 MHz were used with best results obtained between 40 and 100 MHz. Surface impedance and magnetic induction techniques were also used to obtain a separate control on vertical inhomogeneity. Soil samples were tested for organic and water content. The dielectric constants determined for the ice-rich organic sults stagged from 40 to 55 while those for the sands and gravels were about 51. Dielectric loss was due to d.c. enduction and was very low for the silts but significant for the sands and gravels were most likely due to the higher concentrations of salt that are reported to easist in the old beach ridges in this region. All the RFI measurements are believed to be indicative of only the first few meters of the ground although the radiowaves could penetrate to tens of meters.

CR #1-15 STATISTICAL EVALUATION OF SOIL AND CLIMATIC PARAMETERS AFFECTING THE CHANGE IN PAVEMENT DEFLECTION DUR-

ING THAWING OF SUBGRADES Chamberlain, E.J., July 1981, 10p., ADA-106-976, 7 refs.

PAVEMENTS, DEFORMATION, SEASONAL FREEZE THAW, SUBGRADE SOILS, LOADS (FORCES), CLIMATIC FACTORS, FROST PENE-TRATION, STATISTICAL ANALYSIS

This report analyzes the results of a field study previously reported by Seriyner et al (1969) for the National Cooperative

Highway Research Program These authors studied the seasonal pavement deflection characteristics of 24 test sites seasonal pavement deflection characteristics of 24 test sites on roads in service in regions with freezing indexes ranging from 100F-days to 2100F-days. They used the Dynaffect cyclic pavement loading device to determine the pavement system response. Of specific interest to the analysis was the increased pavement deflection after freezing and thawing and the time to recovery of normal deflection characteristics. These characteristics were related to soil and climatic factors using estatical techniques. The most using fact between using statistical techniques The most significant observa-tions of this statistical analysis are: 1) that the freezing index is not a significant parameter in determining the percent increase in pavement deflection during thawing, and 2) that of freezing. As was expected, the most significant variable affecting the increase in pavement deflection was the frost susceptibility classification. This observation reinforces the sity for careful selection of soil materials used in pavement systems.

CR 81-16 COLD REGIONS TESTING OF AN AIR-TRANS-PORTABLE SHELTER.

Flanders, S.N., Aug. 1981, 20p., ADA-107 131, 9 refs.

PORTABLE SHELTERS, TRANSPORTATION.
COLD WEATHER PERFORMANCE. AIR-PLANES, TESTS.

PLANES, TESTS.

An air-transportable shelter designed and built at CRREL for use in cold regions underwent testing in Hanover. New Hampshire, and Ft Greely, Alaska The shelter demonstrated some of its capabilities for mobility by being towed for more than 60 miles behind various vehicles and by being transported on a C-130 cargo airplane, a CH-47 helicopter, and a trailer truck. The shelter proved to be very easy for a crew of two to four to set up in all weather conditions including -40F cold However, the gasoline-powered generator, which was a source for space heat as well as electricity, functioned very poorly Overall, the prototype successfully demonstrated qualities of self-reliance, ease of operation and thermal efficiency

CR 81-18 CHENA RIVER LAKES PROJECT REVEGETA-TION STUDY-THREE-YEAR SUMMARY. Johnson, L.A., et al., Oct. 1981, 59p., ADA-108 909.

Rindge, S.D., Gaskin, D A. 36-2222

REVEGETATION, GRASSES, GROWTH, SOIL STABILIZATION, GRAVEL, VEGETATION, UNITED STATES—ALASKA FAIRBANKS.

DVITED STATES—ALASKA - FAREDANAS.

During the growing seasons of 1977, 1978 and 1979, revegetation techniques were studied on the Chena River Lakes
Project a flood control dam and levee near Fairbanks, Alaska,
to find an optimal treatment for establishing permanent vegetation cover on the gravel structures. The treatments tested Project a flood control dam and levee near Fairbanks, Alaska, to find an optimal treatment for establishing permanent vegetation cover on the gravel structures. The treatments tested on plots at the dam and/or levee involved three main variables. I) vegetation (grass and clover seed and or willow cuttings). 2) mulch, mulch blanket, and or sludge and 3) substrate (gravel or fine-grained soil over the gravel base). The mulches were hay, weed-cellulose-fiber, peat moss, and Conwed Hydro Mulch 2000, which is a wood-cellulose-fiber mulch with a polysacchande tackifier. A constant rate of fertilizer was applied to all plots except the control. A section of each plot was refertilized again in their third growing season to compare annual and bannual fertilization. The high fertilization rate produced above-average growth bescue, brome, and fostail were the most productive species on the dam, while alishe clover was the most productive on the wetter levee site. When grass seed and willow cuttings were planted at the same time, willow sursival and growth were reduced. Fertilization is required for at least two years to produce an acceptable permanent vegeta. and growth were reduced. Fertilization is required to at least two years to prosluce an acceptable permanent segetation cover, although fine grained soil or sludge reduces the amount of fertilizer needed in the second year. Third year fertilization may be necessary since the benefits of the second fertilization continue for at least two years. A sludge treatment refertilized during its second growing season produces the highest biomass recorded in this stads. Shadge

from the Fairbanks treatment plant poses little, if any, danger of contamination from heavy metals or pathogens year-old seedlings of willow and native woody species growing on the dam do not have deeply penetrating root systems and therefore don't appear to pose an early threat of leakage through the dam.

CR 81-19 GROUND-TRUTH OBSERVATIONS OF ICE-COVERED NORTH SLOPE LAKES IMAGES BY

Weeks, W.F., et al, Oct. 1981, 17p, ADA-108 342, 5 refe

Gow, A.J., Schertler, R.J. 38-4414

LAKE ICE, ICE COVER THICKNESS, RADAR ECHOES, ICEBOUND LAKES, ICE WATER IN-TERFACE, SIDE LOOKING RADAR, UNITED STATES—ALASKA—NORTH SLOPE.

STATES—ALASKA—NORTH SLOPE.
Field observations support the interpretation that differences in the strength of radar returns from the see covers of lakes on the North Slope of Alaska can be used to determine where the lake is frozen completely to the bottom. An acciffrozen soil interface is indicated by a weak return and an ice water interface by a strong return. The immediate value of this result is that SLAR (side-looking airborne radar) imagery can now be used to prepare maps of large areas of the North Slope showing when, the lakes are shallower or deeper than 1.7 m (the approximate draft of the lake ice at the time of the SLAR flights). The bathymetry of these shallow lakes is largely unknown and is not obvious from their sizes or outlines. Such information could be very useful, for example in finding suitable year-round water supplies. supplies

CR 81-20 SHALLOW SNOW MODEL FOR PREDICTING VEHICLE PERFORMANCE.

Harrison, W.L., Oct. 1981, 21p., ADA-108 343, 63

39-1261 SNOW ACCUMULATION, MOTOR VEHICLES, COLD WEATHER PERFORMANCE, TRACTION, SNOW COVER EFFECT, ICE COVER EFFECT, SLUSH, SNOW DEPTH, GROUND THAW-ING, FORECASTING, MODELS.

A historical review of research is presented to establish the state-of-the-art for analyzing the behavior of vehicles in shallow snow. From this review, the most comprehensive and promoting model is put together to establish a first-cut performance prediction model for vehicles operating in shallow snow, slush, ice and thawing soils.

CR 81-21 NEAR-INFRARED REFLECTANCE OF SNOW-COVERED SUBSTRATES.

O'Brien, H.W., et al. Nov. 1981, 17p., ADA-110 868,

Koh G 36-2431

SNOW COVER EFFECT, SOLAR RADIATION. REFLECTION, SUBSTRATES, ICE CRYSTAL OP-RADIOMETRY, METEOROLOGICAL

The reflection of solar radiation by a snow cover in situ and the apparent influence of selected substrates were examined in wavelength bands centered at 0.81, 1.04, 1.10, 1.30, 1.50 and 1.80 micrometers. Substrates included winter wheat. and 1 au microscers it into the property of "crusty" snow and ice Reasonable qualitative agreement between measurements and theoretical predictions was demonstrated. retween measurements and theoretical predictions as demonstrated, with indications of quantitative agreement in the definition of a "semi-infinite depth" of snow cover. It was concluded that ultimate quantitative agreement between theory and measurement will require that an "optically effective grain size" be defined in terms of physically measurable dimensions or meteoriologically predictable characteristics of the ice crystals composing the snow pack

CR 81-22 ICE DISTRIBUTION AND WINTER SURFACE CIRCULATION PATTERNS, KACHEMAK BAY, ALASKA

Gatto, I. W., Dec 1981, 43p., ADA-110 806, 20 refs. 36-2432

ICE CONDITIONS, SEA ICE DISTRIBUTION. OCEAN CURRENTS, SUSPENDED SEDI-MENTS, REMOTE SENSING, LANDSAT, UNIT-ED STATES ALASKA KACHEMAK BAY.

Development of the hydropower potential of Bradley Lake, Alaska, would nearly double winter freshwater discharge from Visaka, would nearly double winter freshwater discharge from the Bradles River into upper Kachemak Bay, and the Copys of Engineers is concerned about possible subsequent increased are formation and related ice-induced problems. The objectives of this investigation were to describe winter surface circulation in the bay and document ice distribution patterns for predicting where additional ice might be transported if forms. Fifts one Landau MSS hand S and T and RBV images with TOT cloud cover or less, taken between Society and the April cach year, were analyzed for the eight winters from 1972 to 1980 with standard photoniter pretation techniques. Results of this analysis showed that elast a softween the distance of the Sachemak Bay acts as a pretation techniques Results of this analysis showed that glavial sediment discharged into Kachemak Bas acts as a natural tracer in the water. Innet kachemak Bas circulation in the winter is predominantly counterclockwise, with

northeasterly nearshore currents along the south shore and southwesterly nearshore currents along the north shore Most of the ice in the inner bay forms at its northeast end and is ducharged by the Fox, Sheep and Bradley Rivers. Some ice becomes shorefast on the tidal flats at the head of the bay, while some moves southwestward along the north shore pushed by winds and currents.

Tanii, K.K., Iskandar, I.K.

36-2284

WASTE TREATMENT, LEACHING, LAND REC-LAMATION, WATER FLOW, SOIL CHEMISTRY. MODELS

A model is presented that consists of a water flow submodel and a nitrogen flow submodel. Irrigation, precipitation, evapotranspiration, surface return flow, and deep percolation are considered in the water flow submodel. The processes of sitrification, dentification, mineralization, immobilization, plant uptake, and nitropen fisation are included in the nitrogen flow submodel. The model has been applied to two sets of experimental data obtained from 1) controlled test cells at U.S. Army Cold Regions Research and Engineering Laboratory in Hanover, New Hampshire, and 2) field plots of the University of California at Davis. Comparison between the experimental and model results indicates the potential expublishies of compartmental models in predicting nitrogen behavior in soil-water-plant systems under wastewater land treatment operations. This model is applicable to slow rate, rapid infiltration, and overland flow systems. A model is presented that consists of a water flow sul

HEAT LOSS, UNDERGROUND PIPELINES, HEATING, PUMPS, TEMPERATURE EFFECTS, ANALYSIS (MATHEMATICS, COST ANALYSIS, SOIL TEMPERATURE, COMPUTER PRO-TEMPERATURE. COMPUTER GRAMS.

This report develops a method of analysis for heat transmission systems operating under district heating load conditions.

The use of thermal energy storage systems is outlined and advantages are given. The method accounts for the effects stages are given. The method ac of heat source and load characteristics. The transmission model itself considers the following technical aspects. I) frictional pressure losses in piping systems, 2) pump characteristics, 3) pump driver characteristics, and 4) heat losses from the burned piping. The capital costs considered are the piping system and necessary pumps. Operation and maintenance costs include cost of heat loss and cost of pumping energy input. Allowances are also made for system maintenance and repair over the assumed lifetime. The heat transmission problem is formulated in the forms of a two-dimensional optimization problem. The decision variables are pipe diameter and supply temperature. The problem is solved by direct search techniques using a Hooke-Jeeves pattern search algorithm. Parametric results are presented along with suggestions for further work. The transe

MECHANICS OF CUTTING AND BORING. PART 7: DYNAMICS AND ENERGETICS OF AXIAL ROTATION MACHINES.

Mellor, M., Dec. 1981, 38p., ADA-113-931, 10 refs 36-3110

PERMAFROST, ROCK DRILLING. EQUIPMENT, THERMAL EFFECTS, DRILLING FLUIDS, ANALYSIS (MATHEMATICS)

This report deals with force, torque, energy and power in machines such as drille and boring devices where the cutting head rotates about a central axis while penetrating parallel to that axis. Starting from a consideration of the forces

developed on individual cutting tools, or segments of cutters, the thrust and torque on a complete cutting head is assessed, and simple relationships between thrust and torque are derived Similarly, the energy and power needed to drive the cutting head are estimated and related to tool characteristics. Design characteristics of existing machines are compiled and analyzed to give indications of thrust, torque, power, effective tool forces, nominal thrust pressure, power density, and specific

SEDIMENTOLOGICAL CHARACTERISTICS AND CLASSIFICATION OF DEPOSITIONAL PROCESSES AND DEPOSITS IN THE GLACIAL ENVIRONMENT.

Lawson, D.E., Dec. 1981, 16p., ADA-113 261, 33 refs. 36-2754

GLACIAL DEPOSITS, GLACIOLOGY, SEDI-MENTATION, GLACIER OSCILLATION, PERI-GLACIAL PROCESSES, GLACIER FLOW, ENVI-RONMENTS CLASSIFICATIONS

Existing classifications for deposits in the glacial envir Ensting classifications for deposits in the glacial environment are inadequate and inconsistent. Deposits should be classified both descriptively and genetically, adequate descriptive classifications already exist. A major problem for previous genetic classifications has been that glacial deposition and the resulting deposits' properties were ponely understood. On the basis of these criteria—ediment source, uniqueness to the glacial environment, and preservation of glacier-derived properties—deposits in the glacial environment result from eather of these terms of preservation of these terms. properties—deposits in the glacial environment result from either of two groups of processes, primary or secondary. Primary processes release the debris of the glacier directly and form deposits that may bear properties related to the glacier and its mechanics. Their deposits are classified genetically as till and are the only deposits indicative of glaciation. In contrast, secondary processes mobility, rework, transport and resediment debris and deposits in the elacial environment. work, transport and resediment debris and deposits in the glacial environment. They develop new, nonglacial properties in their deposits, while destroying or substantially modifying glacier-derived properties. Interpretation of their properties may provide information on the depositional process and/or the local depositional avironment. Secondary deposits are resedimented and therefore not till. They are classified genetically according to the depositional process just as they are in other sedimentary environments. This genetic classification differs from previous classifications in that not all dismittons deposited in the glacial environment are classified as till, it is based strictly on process-related enteria. The origin of properties of glacial deposits in relation to glacier mechanics and environment must be recognized if the mechanisms and depositional processes of former glaciers are to be precisely understood.

EMATICAL MODELS.

Several proposed methods for treating the momentum flun between disting sea are and the underlying ocean are interpreted in terms of simple planetary-houndary-layer (PBL) turbulence theory. The classical two-layer approach, in which the solution for a thin surface layer is matched to an Elman solution for the outer layer, is used to derive several forms for the drag law. These forms range from linear (where stream is proportional to relative speed), through quadratic drag on geostrophic wind in the atmosphere. Only formulations which conform with Routhy-similarity scaling are consistent with free-dorld data from the 1975 AIDJEX drift station. ent with free-derit data from the 1975 AIDJEX draft station experiment. We show how a two-layer model, in thickness, provides an analytic solution for the steady-state PBL equation quite similar to recent numerical solutions. The theory is extended to include drag reduction due to biosynney from rapid melting and is shown to agree with atmospheric results for genetrophic drag under analogous conditions of radiotional cooling. The theory provides a bases for estimating trajectorics and melt rates of floes diriting into water warmer than the new meltions terminature.

ON THE TEMPERATURE DISTRIBUTION IN AN AIR-VENTILATED SNOW LAYER. Yen, Y.-C., Mar. 1982, 10p., ADA-115 598, 9 refs.

TEMPERATURE, HEAT TRANSFER, MASS TRANSFER. TEMPERATURE GRADI-ENTS. FLOW RATE, TEMPERATURE DISTRI-BUTION, DIURNAL VARIATIONS, ANALYSIS (MATHEMATICS).

(MATHEMATICS).

The problem of simultaneous heat and main transfer in a homogeneous snow layer, with one side kept at its initial temperature and the other side with a step temperature increase, was solved for the case of constant through-flow conditions. An experimentally determined effective thermal conductivity function, i.e. Ke. 0.0014±0.58. G (where G is dry mass flow rate of air in g.cm2s), was employed in the solution. The computed nondimensional temperature distribution agreed quite well with experimental data taken under pseudo-steady state conditions with the exception of the temperature for the lowest flow rate used in the experiment. The pronounced nonlinearity of the temperature distribution. For the temperature for the lowest flow rate used in the experiment. The pronounced nonlinearity of the temperature distribution was found to be a strong function of the flow rate. For strussoidal variation of atmospheric pressure, the responding flow in the shoot medium was also found to be sommoded in conjunction with the desiral temperature change, this variation facilitated the process of repeated sublimination and condensation in alternate directions and thereby produced a surface layer of appearametely constant show density.

MEASUREMENT OF GROUND DIELECTRIC PROPERTIES USING WIDE-ANGLE REFLEC-TION AND REFRACTION

Arcone, S.A., et al, Mar. 1982, 11p., ADA-119 596, 11

Delaney, A J 40-4674

FROST HEAVE, SOIL FREEZING, ICE MODELS. REGELATION, ICE FORMATION, GROUNDED ICE, HEAT TRANSFER, MASS TRANSFER, THERMODYNAMICS, ANALYSIS (MATH-

EMATICS).

In this paper, frost heave is analyzed for the common case in which some nee penetrates the soil. In this setuition, heave is due to the accumulation of soil-free nee paid within the frozen zone, behind a frozen fringe of finite thechaes. Heat and mans transport within and across that fringe are crucial processes in the dynamics of heave. This analysis concentrates on activity within the fringe, also connecting that activity to heat and mans flows in the more frozen and unfrient zones. Each component in a set of governing differential equations in developed from rational physics and thermodynamics, using previous experimental work. It differential equations is developed from rational physics and thermodynamics, using previous experimental work. It is assumed that the soil see grows through interconnected interstices, hence it constitutes and can move as a rigid holy. When this assumption it translated into mathematical terms, it completes the governing equations. The model resoliting from these considerations is a one-dimensional finite element computer program that solves the equations for arbitrary notical and boundary conditions. The model is need to simulate the heavy business of a hypothetical sol column frozen unadirectionally and subjected to a surcharge The results are grandings in that they predict qualitative fiber characteristics of assumerous laborators observations. Some questions about the completeness of the theory remains and strict verification of the model as any further experimentation and better parameter identification.

CHEMICAL ICE PREVENTION, ICE CONTROL, SALTING, ROAD ICING, SNOW REMOVAL, ICE REMOVAL, SAFETY, FRICTION, TRAFFICA-BILITY.

Snow and ice control on highways has come to rely heavily Snow and ice control on highways has come to rely heavily on the sodium, chloride to maintain a trafficable surface for unimpeded movement Empirical approaches have led to a wide range of application rates, some clearly excessive, but justified on the ground of safety and expediency. The combination of environmental degradation from the huge quantities of salt entering the environment, along with the increased cost of salt itself and the cost of its application have spurred the search for more precise knowledge of the have spurred the search for more precise knowledge of the proper amount of salt to apply to a pavement, considering a range of environmental, traffic and chemical parameters. Since controlled tests in the field are extremely difficult to make, a circular test track of three test pavements, densegraded asphalitic concrete (DGA), open-graded asphalitic concrete (OGA) and portland cement concrete (PCC), was constructed in a coldrom. Natural snow and ice were applied to the pavements and an instrumented slipping wheel was driven over the surfaces to generate frictional forces. These forces were measured and then used to evaluate the response to salt application with time for three test temperature oGA had the lowest friction values at a temperature near the freezing point, but higher initial values or more rapidly increasing values than DGA and PCC following salt application rate at the two lower temperatures. at the two lower temperatures Optimum application rate of salt on PCC and DGA lies between 100 and 300 lb/lane mile (LM), and a higher rate resulted in slight or no improvement in friction. DGA showed anomalous results lower friction for 300 lb/LM and higher friction for both 100 and 500 lb/LM.

DECELERATION OF PROJECTILES IN SNOW. ..ibert, D.G., et al, Aug 1982, 29p, ADA-119 676, 11 refs.

Richmond, P.W.

SNOW DENSITY, PENETRATION TESTS, PRO-JECTILE PENETRATION, MILITARY SEARCH, VELOCITY, IMPACT STRENGTH

Instrumented M374 projectiles were launched into snow, nylon, and Styrofoam targets using a 16.7-m radius centrifuge. For snow of 410-kg/cu m density, the 31-kg test projectile experienced decelerations of approximately 220, 400, and 550 m/sq s (at a depth of 0.1 m) for initial impact velocities of 15, 30 and 46 m/s respectively. These values disagree with values predicted from a simple hydrodynamic drag force approximation. The decelerations measured for snow the approximation and a decertainties included to show the largets were always greater than those measured for nylon shaving targets (of density 120 kg/cu m) indicating that this material is not a good analog for snow of the density used in these tests

CR 82-21 ACOUSTIC EMISSIONS FROM POLYCRYS-TALLINE ICE.

St Lawrence, W F, et al, Aug 1982, 15p, ADA-119 632, 18 refs

Cole, D.M.

ICE CRYSTAL STRUCTURE, ICE ACOUSTICS, COMPRESSIVE PROPERTIES, STATIC LOADS, FRACTURING, STRESSES, STRAINS, TEMPER-ATURE EFFECTS, TIME FACTOR, TESTS

The acoustic emission response from fine-grained polycrystaline ice subjected to constant compressive loads was examined. A number of tests were conducted with the normal stress ranging from 0.8 to 3.67 MPa at a temperature of -5 C. The acoustic emission response was recorded and the data are presented with respect to time and strain. The source of acoustic emissions in ice is considered in terms of the formation of both microfractures and visible fractures that develop without catastrophic failure of the ice. A model of designed the acoustic emissions in the consideration is developed. describe the acoustic emission response is developed

CR 82-22 CONDUCTION PHASE CHANGE BENEATH INSULATED HEATED OR COOLED STRUC-THRES

Lunardini, V.J., Aug. 1982, 40p., ADA-119 595, 19

39-1746

PERMAFROST BENEATH STRUCTURES, PER MAFROST HEAT TRANSFER, FREEZE THAW CYCLES, CONDUCTION, HEAT TRANSFER, PHASE TRANSFORMATIONS, UNDER-PHASE TRANSFORMATIONS, GROUND PIPELINES, THERMAL TION, ANALYSIS (MATHEMATICS).

The problem of thaving beneath heated structures on perma-frost (or cooled structures in non-permafrost zones) must be addressed if safe engineering designs are to be conceived. In general there are no exact solutions to the problem of conduction heat transfer with phase change for practical conduction heat transfer with phase change for practical geometries. The quasi-steady approximation is used here to solve the conductive heat transfer problem with phase change for insulated geometries including infinite strips, rectangular buildings, circular storage tanks, and buried pipes. Analytical solutions are presented and graphed for a range of parameters of practical importance.

DIRECT FILTRATION OF STREAMBORNE GLACIAL SILT.

Ross, M.D., et al, Sep. 1982, 17p, ADA-120 751, 8

Lowman, R.A., Sletten, R.S.

SEDIMENTS, GLACIAL DEPOSITS, GLACIAL RIVERS, WATER TREATMENT, GEOLOGICAL SURVEYS, EQUIPMENT.

SURVEYS, EQUIPMENT.

A direct filtration, water treatment pilot plant was operated on the Kenai River at Soldotna, Alaska, during the summer of 1980. The purpose of the pilot plant operations was to determine the feasibility of the direct filtration process for removal of glacual silt. The major criterion used to determine feasibility was production of water containing less than 10 NTU of turbidity. For the range of raw water turbidities encountered (22-34 NTU), the pilot plant testing indicated that direct filtration was feasible and could be considered as an alternative to conventional water treatment plants containing sedimentation tanks. plants containing sedimentation tanks

SUBSEA PERMAFROST IN HARRISON BAY, ALASKA: AN INTERPRETATION FROM SEIS-MIC DATA.

Neave, K.G., et al, Aug. 1982, 62p., ADA-121 020, 16 refs

Sellmann, P.V.

SUBSEA PERMAFROST, SEISMIC SURVEYS, BOTTOM SEDIMENT, SEISMIC REFRACTION, SEISMOLOGY, NATURAL RESOURCES, OCEAN BOTTOM, UNITED STATES—ALASKA—HARRISON BAY.

Velocity data derived from petroleum industry seismic records from Harrison Bay show that high-velocity material (>2km/s) interpreted to be ice-bonded permafrost is common in the eastern part of the bay, the depth to high velocity material increases and velocity decreases in an orderly manner material increases and velocity decreases in an orderly manner with increasing distance from shore until the layer is no longer apparent. The western part of the bay is less orderly, possibly reflecting a different geological and thermal history. This western part may be an inundated section of the low coastal plain characterized by the region north of Teshekpuk Lake, and could have contained deep thaw lakes, creating low velocity zones. Along some seismic lines, the high-velocity material extends approximately 25 km offshore.

CR 82-25 EXPERIMENTAL INVESTIGATION OF PO-TENTIAL ICING OF THE SPACE SHUTTLE EX-TERNAL TANK.

Ferrick, M.G., et al, Sep. 1982, 305p., ADA-121 330 Itagaki, K., Lemieux, G.E., Minas, S.E.

AIRCRAFT ICING, TANKS SPACECRAFT. PROTECTIVE COATINGS. THERMAL INSULATION, ICE FORMATION, COUNTERMEASURES, SURFACE TEMPERA-TURE, STATISTICAL ANALYSIS, EXPERIMEN-TATION.

The thermal protection system tiles on the space shuttle Orbiter are extremely sensitive to impact damage. Such impacts could be caused by ice particles dislodged from the outer surface of the external tank (Ef) during the launch the outer surface of the external tank (EI) during the launch. The ET, which contains the cryogenic propellant tanks, is covered with a spray-on foam insulation (SOFI) to minimize use formation. The objective of this investigation was to experimentally explore a range of environmental conditions for which significant using potential exists for the ET. Significant finding, which became evident early in the experimental program, was that computer models based upon the average SOFI thickness predicted panel surface temperatures that were considerably higher than those observed. For an assessment of icing, the important values to characterize

the SOFI are the minimum thickness and range of thickness. Dense ice formation occurred most readily when a small portion of the total surface area had a temperature below

WATERSHEDS, DRAINAGE, PERMAFROST HYDROLOGY, CLIMATE, RUNOFF, STREAM FLOW, PRECIPITATION (METE/SROLOGY), SEASONAL VARIATIONS, UNITED STATES— ALASKA—CARIBOU CREEK.

ALASKA—CARIBOU CREEK.
The Carbou-Poker Creeks Research Watershed is a small drainage basin located 48 km northwest of Fairbanks, Alaska Elevations within the watershed range from 210 to 826 m, and approximately 28% of its area is underlain by permaferiors. Climatic differences between the watershed and Fairbanks Comparison between the watershed and Fairbanks are primarily due to the higher elevation of watershed. Generally the watershed climatic sites are warmer in winter and cooler in summer than Fairbanks. An analysis of annual streamflow data showed an inconsistency of baseflow recessions from year to year. The runoff-rainfall ratio for individual summer storms averaged 0.35 for Carbou Creek. Comparisons of spot discharge measurements of predominantly permafrost and non-permafrost subwatersheds showed that permafrost-dominated watersheds have a much "flashier" response to precipitation than non-permafrost watersheds. A comparison of the annual flow distribution of the watershed indicated that Carbou Creek has lower summer and higher winter discharges per unit area than the Chena or Salcha Rivers. The temporal variability of the flow of Caribou Creek is low compared with small- and moderate-sized streams in New England.

CR 82-27 LEAST LIFE-CYCLE COSTS FOR INSULATION

IN ALASKA. Flanders, S.N, et al, Oct 1982, 47p, ADA-122 806, 6 refs.

Coutts, H.J. 37-1482

THERMAL INSULATION, BUILDINGS, COST ANALYSIS, ECONOMIC ANALYSIS, CLIMATIC FACTORS, FUELS, MILITARY FACILITIES.

FACTORS, FUELS, MILITARY FACILITIES.

Recommendations for economical thicknesses for building insulation result from a study of fuel and construction costs of 12 military installations in Alaska. A comparison between the insulation thickness that a building owner might choose today and what he might choose in 20 years indicates a trend for much thicker insulation in the future of how much more expensive a building built today with the thickness that would be appropriate 20 years hence indicates only a small penalty in life-cycle costs for the additional insulation. Therefore, a minimum of R-32 walls and R-62 attics is recommended for most of Alaska

CR 82-28 EVALUATION OF VAISALA'S MICROCORA AUTOMATIC SOUNDING SYSTEM.

Andreas, E.L., et al. Oct. 1982, 17p., ADB-070 011L, 17 refs.

37-1529

MARINE METEOROLOGY, METEOROLOGI-CAL INSTRUMENTS, METEOROLOGICAL DATA, WIND (METEOROLOGY).

DATA, WIND (METEOROLOGY).

During the Weddell Polynya Expedition in the southern occan, over 60 upper-air soundings were made with a Vaisala MicroCORA Automatic Sounding System installed on the Soviet tecbreaker Mikhail Somov The MicroCORA system measures the wind vector by using the Omega navaid signals to track the balloon-borne radiosonde This windfinding the formula station, measures the wind vector by using the Omega navaid signals to track the balloon-borne radiosonde. This windfinding is thus unaffected by any motions of the ground station, the system is easy to use, and the data seem accurate Comparison launches, during which the Vassals radiosonde and the sonde of another manufact rer were carried on the same balloon, indicate that the MicroCORA pressure and temperature data are also of high quality. There were problems with the MicroCORA measurement of humidity however, because of an mordinate number of failures. were problems with the MicrocOKA measurement of number, however, because of an inordinate number of failures of the humidity sensor, the Humicap, which is prone to drift. After a unit-by-unit hardware evaluation of the components of the MicroCOKA system, its expected reliability for use at sea is judged only fair, several units were poorly packaged, and servicing and repair require a high degree of technical expectises. GROWTH OF FACETED CRYSTALS IN A SNOW COVER.

Colbeck, S.C., Oct. 1982, 19p., ADA-122 792, 45 refs 37-1722

SNOW CRYSTAL GROWTH, RECRYSTALLIZA TION, SNOW CRUST, DEPTH HOAR, HEAT FLUX, VAPOR TRANSFER, GRAIN SIZE, THER-MODYNAMICS, SNOW DENSITY, TEMPERA-URE EFFECTS, TEMPERATURE GRADIENTS. SNOW COVER.

lce grains in a snow cover with a low temperature gradient assume a well-rounded equilibrium form. However, at temperature gradients of 0 1 to 0.2C/cm (depending somewhat on temperature and snow density), the rounded grains recrystalize into a faceted kinetic growth form. The lar temperature gradient must play a decisive role in mover fast enough to sustain the rapid growth rate to the faceted growth form. Once the large gradient is removed, the grains recrystallize of the equilibrium form. The recrystallization occur in either direction without a change in bulk density. The growth of faceted crystals begins at the warmer base of the snow cover where the excess vapor pressure is largest. A transition between the overlying rounded grains moves upward in time. Faceted crystals also grow just below crusts of reduced permeability, where the increased vapor accumulation can sustain the excess vapor pressure needed for kinetic growth. The heat and vapor flows are described using a model based on thermodynamic equilibrium. The temperature distribution is shown to be quasi-linear at steady state in homogeneous snow. The recrystallization of the snow is modeled using the rounded grains as sources and the faceted grains as sinks. In the future this model should be extended to account for different temperatures among the sources and sinks.

PLICATIONS, ANALYSIS (MATHEMATICS). Equations are developed that can be used to determine the amount of gas present in sea ice from measurements of the bulk ice density, salinity and temperature range of -2 to -30C. Conversely these relationsips can be used to give the density of sea ice as a function of its temperature and salinity, considering both the presence of gas and of solid salits in the ice. Equations are also given that sllow the calculation of the gas and brine volumes in the ice at temperatures other than that at which the bulk density was determined

CR 82-31 BERING STRAIT SEA ICE AND THE FAIRWAY ROCK ICEFOOT

Kovacs, A., et al, Oct. 1982, 40p, ADA-122 477, 45

Sodhi, D.S., Cox, G.F N.

39-1273

ICE CONDITIONS, SEA ICE, PRESSURE RIDGES, ICE PRESSURE, ICE FORMATION, OFFSHORE LANDFORMS, ICE LOADS, GROUNDED ICE, AERIAL SURVEYS, BERING

Information on sea ice conditions in the Bering Strait and the icefoot formation around Fairway Rock, located in the strait, is presented. Cross-sectional profiles of Fairway Rock and the relief of the icefoot are given along with theoretical analyses of the possible forces active during icefoot formation. It is shown that the ice cover most likely fails in flexure as opposed to crushing or buckling, as the former requires less force. Field observations reveal that the Fairway Rock icefoot is massive, with ridges up to 15 m high, a seward face only 20 deg from vertical, and interior ridge slopes averaging 33 deg. The icefoot is believed to be grounded and its width ranges from less than 10 to over 100 m. Information on sea ice conditions in the Bering Strait and

FLUID DYNAMIC ANALYSIS OF VOLCANIC TREMOR.

Ferrick, M.G, et al, Oct 1982, 12p, ADA-122 778, 28 refs.

Qamar, A., St Lawrence, W.F.

DYNAMICS SEISMOLOGY. FILLID CANOES, EARTHQUAKES, ICEQUAKES, GEO-MAGNETISM.

MAGNETISM.

Low-frequency (< 10 Hz) volcanic earthquakes originate at a wide range of depths and occur before, during, and after magmatic eruptions. The characteristics of these earthquakes suggest that they are not typical tectonic events. Physically analogous processes occur in hydraulic fracturing of rock formations, low-frequency lecquakes in temperate glaciers, and autoresonance in hydroelectric power stations. We propose that unsteady fluid flow in volcanic conduits is the common source mechanism of low-frequency locanic earthquakes (tremor). The fluid dynamic source mechanism explains low-frequency carthquakes of arbitrary duration, magnitude, and depth of origin, as unsteady flow is independent of physical properties of the fluid and conduit. Fluid transients occur in both low-isscotity gates and high-viscotity liquids. A fluid transients on the formulated as generally as its warranted by knowledge of the composition and physical properties of the fluid, material properties geometry and roughness of the conduit, and boundary conditions

CR 82-33 ON THE DIFFERENCES IN ABLATION SEA-SONS OF ARCTIC AND ANTARCTIC SEA ICE. Andreas, E.L., et al, Oct. 1982, 9p., ADA-122 454, 41 refs. For another source see 36-2836 (MP 1517). Ackley, S.F. 39-1728

SEA ICE, ICE MELTING, ABLATION, METEOROLOGICAL FACTORS, ICE CONDI-TIONS.

Arctic sea ice is freckled with melt ponds during the ablation season, Antarctic sea ice has few, if any On the basis of a simple surface heat budget, we investigate the meteorological conditions necessary for the onset of surface melting in an attempt to explain these observations. The low relative hund y associated with the relatively dry winds off the continent and an effective radiation parameter smaller than that characteristic of the Arctic are primally responsible. off the continent and an effective radiation parameter smaller than that characteristic of the Arctic are primarily responsible for the absence of melt features in the Antarctic Together these require a surface-layer air temperature above 0 C before Antarctic sea tee can melt A ratio of the bulk transfer coefficients C(H)/C(E) less than 1 also contributes to the dissimilarity in Arctic and Antarctic ablation seasons. The effects of wind speed and of the sea-ice roughness on the absolute values of C(H) and C(E) seem to moderate regional differences, but final assessment of this hypothesis awaits better data, especially from the Antarctic

HYDRAULIC MODEL STUDY OF PORT HURON ICE CONTROL STRUCTURE. Calkins, D J., et al, Nov. 1982, 59p., ADA-123 715, 8

FLOES, DOPED ICE, PORTS, MODELS.

The tee discharge through an opening in an ice control structure was documented to be a function of the fibe size, tee type, ice floe conditions and vessel direction. The model data for the average ice discharge per vessel transit scaled to prototype values compared favorably with data taken at the St. Marys River ice control structure (ICS). The model results of the force measurements were also consistent with data taken at the St. Marys ICS. The dynamic loading conditions were independent of vessel direction. The dynamic loading to the structure using 3 types of ice (plastic, natural and urea-doped) showed a considerable difference in their means and standard deviations. The urea-doped ice was evaluated for dynamic loading conditions, and reasonable peak values of 3 to 5 times the mean load at each measuring position were recorded, independent of vessel direction. It appears that synthetic random ice floes may be used in model studies where ice discharge through an opening in a structure needs to be documented. This study shows the synthetic random ice floe discharge to fall reasonably within the values obtained for natural codischarge for both rafted and non-rafted ice fields above the ICS. However, the question of whether synthetic can be used for analyzing force distribution ref dynamic force loading criteria cannot be fully answered at this time because the load distributions of the synthetic and natural floes appear to differ

CLIMATE OF REMOTE AREAS IN NORTH-CENTRAL ALASKA: 1975-1979 SUMMARY.

Haugen, R K., Nov. 1982, 110p., ADA-123 719, 31

CLIMATE, SNOW ACCUMULATION, PRECIPI-TATION (METEOROLOGY), AIR TEMPERA-TURE, TEMPERATURE GRADIENTS, STATIS-TICAL ANALYSIS, TEMPERATURE TIONS, UNITED STATES -ALASKA

Air temperature, precipitation, and some ground surface temperatures predominantly from remote areas of central and northern Alaska are statistically and graphically summarized on a monthly basis for a five-year period (1975-79). The remote site data were obtained during the course of several CRRE. Investigations. To provide a more comprehensive coverage, these data are presented together with data obtained at National Weather Service stations (1) the area. The analysis is based on four climatic regions within the study area, the Continental Interior the Brooks Range the Arctic Foothills, and the Arctic Coastal Plain. A detailed analysis of coastal-inland summer air temperature gradients on the Arctic Coastal Plain is given. Station histories for the 1975-79 period and tabulated air and ground temperature statistics are included as appendices. Air temperature, precipitation, and some ground surface tem-

CR 82-36 LONG-TERM MODIFICATIONS OF PERENNI-ALLY FROZEN SEDIMENT AND TERRAIN AT EAST OUMALIK, NORTHERN ALASKA. Lawson, D.E., Nov. 1982, 33p, ADA-123 731, Refs.

PERMAFROST THERMAL PROPERTIES, DEG-RADATION, SOIL EROSION, SEDIMENTS, TUNDRA, ENVIRONMENTAL IMPACT, THER-MOKARST, ACTIVE LAYER, HUMAN FACTORS ENGINEERING, UNITED STATES—ALASKA—OUMALIK.

TORS ENGINEERING, UNITED STATES—
ALASKA—OUMALIK.
Camp construction and drilling activities in 1950 at the East Oumalik drill site in northern Alaska caused extensive degradation of see-rich, perennially frozen silt and irreversible modification of the upland terrain. In a study of the long-term degradational effects at this site, the near-surface geology was defined by drilling and coring 76 holes (maximum depth of 34 m) in disturbed areas and by laboratory analyses of these cores. Terrain disturbances, including buildozed roads and excavations, camp structures and off-road vehicle trails, were found to have severely disrupted the site's thermal regime. This led to a thickening of the active layer, melting of the ground ice, thaw subsidence and thaw consolidation of the sediments. Slumps, sediment gravity flows and collapse of materials on slopes bounding thaw depressions expanded the degradation latersily, with thermal and hydraulic recision removing material as the depressions widened and deepened with time. Degradational processes became less active after thawed sediments theckned sufficiently to slow the increase in the depth of thaw and permit slope stabilization. The site's terrain is now irregular and hummocky with numerous depressions. Seasonal thaw depths are deeper in disturbed areas than in undisturbed areas and reflect the new moisture conditions and morphology. The severity of disturbance is much greater at East Oumalik than at another and the procession of the season of the second of the second of the second of the conditions and morphology. turbed areas than in undisturbed areas and reflect the new monsture conditions and morpholopy. The severity of disturbance is much greater at East Oumalik than at another old drill site. Fish Creek The difference results primarily from differences in the physical properties of the sediments, including the quantity and distribution of ground ice. In areas similar to East Oumalik, the rentioval or severe compaction of the vegetative mat would caus, similar adverse physical changes to take place over two to three decades and should therefore be avoided

LANDSAT-ASSISTED ENVIRONMENTAL. MAPPING IN THE ARCTIC NATIONAL WILD-LIFE REFUGE, ALASKA.

Walker, D A., et al, Nov. 1982, 59p. + 2 maps, ADA-123 440, Refs. p 34-37. Acevedo, W, Everett, K.R, Gaydos, L, Brown, J., Webber, P.J.

This report presents a Landsat-derived land cover map of the northwest portion of the Arctic National Wildlife Refuge, Alaska The report is divided into two parts The the northwest portion of the Arctic National within Refuge, Alaska The report is divided into two parts. The first is devoted to the land cover map with detailed descriptions of the mapping methods and legend. The second part is a description of the study area. The classification system used for the maps is an improvement over existing methods of describing tundra vegetation. It is a comprehensive method of nomenclature that consistently applies the same entering for all vegetation units. It is applicable for largemethod of nomenclature that consistently applies the same criteria for all vegetation units. It is applicable for large-and small-scale mapping and is suitable for describing vegetation complexes, which are common in the patterned-ground terrain of the Alaskan Arctic. The system is applicable to Landsat-derived land cover classifications. The description of the study area focuses on five primary terrain types flat thaw-lake plains, hilly coastal plains, foothills, mountainous terrain, and river flood plains. Topography, landforms, soils and vegetation are described for each terrain type. The report also contains area summaries for the Landsaterised map categories. The area summaries are generated for the five terrain types and for the 89 townships within the study areas. Two land cover maps at 1 250,000 are included.

CR 82-38 WINDOW PERFORMANCE IN EXTREME COLD

Flanders, S N, et al, Dec. 1982, 21p, ADA-124 571, For another version see 35-2514. 10 refs Buska, J. Barrett, S 38-4415

JOINT WINDOWS, WEATHERPROOFING, MILITARY FACILITIES, THERMAL INSULATION, COLD WEATHER CONSTRUCTION, HEAT LOSS, AIR LEAKAGE, HUMIDITY, CONDENSATION, COUNTERMEASURES, COST

A streme cold causes heavy buildup of frost, ice and condensa-tion on many sundows. It also increases the incentive for improving the arrightness of sundows against heat loss. Our study shows that tightening specifications for Alaskan windows to perinit only 30° of the air leakage allowed by current American airtightness standards is economically

attractive. We also recommend triple glazing in much of Alaska to avoid window using in homes and barracks. We base our conclusions on a two-year field study of Alaskan military bases that included recording humidity and temperature data, observing moisture accumulation on windows and measuring airtightness with a fan pressurization device.

CR 82-39 BRINE ZONE IN THE MCMURDO ICE SHELF, ANTARCTICA.

Kovacs, A, et al, Dec. 1982, 28p., ADA-124 516, 29

A.J., Cragin, J.H., Morey, R.M. 37-3355

ICE SHELVES, BRINES, ICE SALINITY, AN-TARCTICA—MCMURDO ICE SHELF.

TARCTICA—MCMURDO ICE SHELF.

A 4.4-m-high brine step in McMurdo Ice Shelf has migrated about 1.2 km in 4 years. This migration is proof of the dynamic nature of the step, which is the leading edge of a brine wave that originated at the shelf edge after a major break-out of the McMurdo Ice Shelf. The inland boundary of brine benetration is characterized by a series of descending steps that are believed to represent terminal positions of separate intrusions of brine of similar origin The inland boundary of brine percolation is probably controlled largely by the depth at which brine encounters the firm/ice transition (43m). However, this boundary is not fixed by permeability considerations alone, since measurable movement of brine is still occurring at the inland boundary Freeze-fractionation of the seawater as it migrates through the ice shelf preferentially precipitates virtually all sodium sulfate, and concomitant removal of water by freezing in all pore spaces of the infiltrated firm produces residual brines approximately six times more concentrated than the original seawater. CYCLE, SURFACE WATER

A slow rate land treatment system that operates throughout the year in a very cold climate is described in detail Information on the geology, soils, vegetation, wildlife and the climate at the site is also presented Winter operational problems such as ice formation on the elevated spray laterals, and freezing and plugging of the spray nozzles are discussed, as are their solutions The detailed results of a 1-year study to characterize the seasonal performance of the system, to develop N and P budgets for the system, to monitor specific hydrologic events on the spray field, to monitor shallow groundwater quality, to monitor the groundwater quality in off-site wells, and to monitor the groundwater quality in off-site wells, and to monitor the Recommendations for the design and operation of other slow rate land treatment systems to be constructed in cold climates are included. are included.

ANALYSIS OF ROOF SNOW LOAD CASE STUDIES; UNIFORM LOADS.
O'Rourke, M, et al, Jan 1983, 29p., ADA-126 330, 12

refs.

Koch, P., Redfield, R. 37-3351

ROOFS, BUILDING CODES, SLOPE ORIENTA-TION, DESIGN, STATISTICAL ANALYSIS

TION, DESIGN, STATISTICAL ANALYSIS.

Roof snow load case studies gathered throughout the United States over a three-year penod are analyzed. The objective of the analysis is to determine a relationship between the snow load on the ground and the corresponding uniform snow load on flat and sloped roofs. The main parameters considered are the thermal characterities of the roof, the roof slope and the exposure of the structure. Exposure has the strongest effect on the ratio of ground to roof snow loads. Comparisons are made with existing and proposed building codes and standards.

COMPUTER MODELING OF TIME-DEPEND-ENT RIME ICING IN THE ATMOSPHERE Lozowski, E.P., et al, Jan 1983, 74p., ADA-126 404, 19 refs.

Oleskiw, M.M. 37-3497

AIRCRAFT ICING, ICE ACCRETION, TIME FACTOR, ICE FORMATION, COMPUTERIZED SIMULATION, HELICOPTERS, MATHEMATICAL MODELS.

A numerical model of time ice accretion on an arbitrary two-dimensional airoit is presented. The physics of the model are described and results are presented that demonstrate, by comparison with other theoretical data and experimental data, that the model predictions are believable. Results are also presented that illustrate the capability of the model to handle time-dependent rime ice accretion, taking into account the feedback between the ice accretion and the sirflow and droplet trajectory fields

CR 83.03 ASSESSMENT OF THE TREATABILITY OF TOXIC ORGANICS BY OVERLAND FLOW. Jenkins, TF, et al, Jan. 1983, 47p, ADA-126 384, Refs. p 28-30.

Leggett, D.C., Parker, L V., Oliphant, J.L., Martel, C.J., Foley, B T., Diener, C.J.

WASTE TREATMENT, WATER TREATMENT, LAND RECLAMATION, TEMPERATURE EF-FECTS, SLOPES, WATER POLLUTION, AB-SORPTION, WATER FLOW

The removal efficiency for 13 trace organics in wastewater was studied on an outdoor, prototype overland flow land treatment system. The removal for each of these substances was greater that 94% at an application rate of 0.4 cm/hr. The percent removals declined as application rates were increased. The rate of removal from solution was described by the sum of two mass-transport limited, first-order rate coefficients representing solutions and sortion. coefficients representing volatilization and sorption. A model based on the two-film theory was developed, the observed removal rate coefficients were regressed against three properties of each substance the Henry's constant, the octanol water partition coefficient and the molecular weight. The dependence of the removal process on temperature was studied and is included along with average water.

depth in the model. The decrease in removal rate as temperature declined is supported by the known dependence of Henry's constant and diffusivity on temperature. The model was validated on a second overland flow system. The surface soil concentrations of the trace organics determined at the end of the experiment suggest that a secondary mechanism renews the surface activity rapidly enough so that contaminants do not build up on the surface, with the possible exception of PCB. Biodegradation is suggested as the predominant secondary mechanism rather than volatilization because substances less volatile than PCB were not found at the end of the experiment. at the end of the experiment

ICE GROWTH ON POST POND, 1973-1982. Gow, A.J., et al, Feb. 1983, 25p., ADA-126 334, 15

ICE GROWTH, ICE DETERIORATION, PONDS,
SNOW ICE, ICE COVER THICKNESS,
METEOROLOGICAL FACTORS, SEASONAL
VARIATIONS, ICE MODELS, DEGREE DAYS,
STEFAN PROBLEM, UNITED STATES—NEW HAMPSHIRE-POST POND.

Measurements and analysis of seasonal ice growth and decay on Post Pond, New Hampshire, for the period 1973-1982 are presented Observations included ice thickness measureobservations included ice thickness measurements, examination of the various ice types contributing to the ice cover, and measurements of meteorological parameters for correlation with and modeling of the ice growth process. The overall nature of ice growth and decay (ice loss) on Post Pond has been ascertained, the seasonal variability in the timing of freeze-up and ice-out and the duration of the ice cover have been determined, and the elationation of ice growth to freeze-up adoptionally records evarelationship of ice growth to freezing-degree-day records eva-lusted on the basis of a Stefan conduction equation modified to deal with ice sheets covered with or free of snow. Ice growth occurs predominantly by the direct freezing of lake growth occurs predominantly by the direct freezing of lake water, but snow ice may compose as much as 50% of the ce cover in winters with higher than average snowfall. Freeze-up leading to the establishment of a stable ice cover occurs during the 4-week period from the end of November to the end of December. Maximum seasonal ice thicknesses were from 45 to 67 cm and are generally attained during the first two weeks of March, ice-out, marking the final disappearance of ice from Post Pond, usually occurs by the third week of April The overall rate of ice loss is three to four times that of ice growth, and is dominated initially by melting from the top. As much as 50% of the ice may be lost in this way before the oiset of any bottom melting Final dissipation of the ice cover is usually expedited by canding resulting from preferential melting and disintegration of the ice at crystal boundaries.

DYNAMIC ICE-STRUCTURE INTERACTION DURING CONTINUOUS CRUSHING, MEBILIBRICH, M., Feb 1983, 48p., ADA-126 349, 22

37-344

ICE SOLID INTERFACE, OFFSHORE STRUC-TURES, PILE STRUCTURES, ICE PRESSURE, DYNAMIC LOADS, ICE LOADS, VELOCITY, TESTS.

This report presents the results of dynamic ice-structure interaction model tests conducted at the CRREL Ice Engineer-Inis report presents the results of oynamic less-stucture metaction model tests conducted at the CRREL Ice Engineering Facility. A flexible, single-pile, bottom-founded offshore structure was simulated by a test pile with about a one-to-ten scale ratio. Urea (instead of sodium chloride) was used as dopant to scale down the ice properties, resulting in good model ice properties. Six ice fields were frozen and 18 tests carried out. In all cases distinctive dynamic ce-structure interaction obstations appeared, from which abundant data were collected. In tests with linear ice velocity sweep, sawtooth-shaped ice force fluctuations occurred first. With increasing velocity the natural in 4es of the test pile were excited, and shifts from one mode. I another occurred The maximum ice force values appeared mostly with low loading rates but high forces appeared randomly at high revelocities. As a general trend, ice force maximums, averages and st. ndard deviations decreased with increasing ice velocities. The aspect ratio effect of the ice force noninuous cruthing follows the same dependence as in static loadings. The frequency of observed ice forces is strongly dominated by the natural modes of the structure. Dynamically unstable natural modes of the structure. Dynamically unstable natural modes tend to make the develop-ing ice force frequencies the same as the natural frequencies

CHEMICAL FRACTIONATION OF BRINE IN THE MCMURDO ICE SHELF, ANTARCTICA. Cragin, J H, et al, Mar 1983, 16p., ADA-127 821, 23

Gow. A.J., Kovacs, A 38-688

ICE CORES, ICE SALINITY, ICE COMPOSITION, ICE SHELVES, ICE PHYSICS, ANTARCTICA MCMURDO SOUND

During the austral summers of 1976-77 and 1978-79, several accords were taken from the McMurdo Ice Shelf brine zone to investigate its thermal, physical and chemical properties. Chemical analyses of brine samples from the youngest (uppermost) brine wave show that it contains sea salts in normal seawater proportions. Further inland, deeper and older brine layers, though slightly highly saline (\$ > 200%), are severely depleted in (\$04)2-/Na+ ratio being an order of magnitude less than that of normal seawater of Na+, K+, Ca2+, Mg2+, (\$64)2- and Cl-, together with solubility and temperature considerations, show that the sulfate depletion is due to selective precipitation of mirrability, Na250410H2O. The location of the inland boundary of brine penetration is closely related to the depth at which the brine encounters the firn/ice transition. However, a small but measurable migration of brine is still occurring in otherwise impermeable ice, this is attributed to cutectuc dissolution of the ice by concentrated brine as it moves into deeper and warmer parts of the McMurdo Ice Shelf (Auth.)

ANALYSIS OF DIFFUSION WAVE FLOW ROUTING MODEL WITH APPLICATION TO FLOW IN TAILWATERS.

Ferrick, M.G., et al, Mar. 1983, 31p, ADA-128 142,

Bilmes, J., Long, S.E.

DAMS, WATER FLOW, WATER WAVES, HYDROLOGY, RIVER FLOW, FLOW MEASUREMENT, MATHEMATICAL MODELS, DIFFU-

Peak power generation with hydropower creates tailwater flow conditions characterized by high and low flows with abrupt transitions between these states Flows occurring abrupt transitions between these states Flows occurring in tailwaters typically form sharp-fronted, large-amplitude waves of relatively short period An understanding of the mechanics of downstream propagation of these waves is important both for direct application in studies of the tailwater and because of the similarity of these waves to those following a dam break An analysis of the dynamic equations of open channel flow is used to quantify the relative importance of each process is related to the relative importance of each process is related to the relative magnitude of terms in the dynamic equations, providing a physical basis for model formulation A one-dimensional diffusion wave flow routing model, modified for tailwaters, simulates the important physical processes affecting the flow and is straightforward to apply. The model is based upon a numerical solution of the kinematic wave equation wave equation

CR 83-08 PROPERTIES OF UREA-DOPED ICE IN THE CRREL TEST BASIN. Hirayama, K., Mar. 1983, 44p, ADA-128 219, 34 refs

DOPED ICE, UREA, ICE STRENGTH, ICE COVER THICKNESS, ICE MECHANICS, HY-DRAULICS, FLEXURAL STRENGTH, ICE MOD-ELS, AIR TEMPERATURE, TESTS.

ELS, AIR TEMPERATURE, TESTS.

In the course of model tests with urea-doped ice in the CRREL lee Engineering Facility test basin, the growth process and the physical and mechanical properties of the model ice were investigated. The parameters which were varied were: urea concentration in the tank water, air temperature during growth, growth duration, and tempering time. Uniformity of ice thickness and ice mechanical properties over the whole tank area were found to be satisfactory. The structure of the urea-doped ice was found to be similar to that of the ice except for a relatively thick incubation layer over a dendritie bottom layer. Empirical relationships were established between ice thickness and negative degree-hours, mechanical properties and growth temperature, urea concentration, and ice thickness, and reduction in mechanical properties and tempering time. The results of the study are presented in charts which permit reliable scheduling of model tests with required ice thickness and ice flexural strength. strength.

SHORE ICE RIDE-UP AND PILE-UP FEA-TURES. PART 1: ALASKA'S BEAUFORT SEA

Kovacs, A., Mar. 1983, 51p., ADA-127 198. 24 refs 38-394

FAST ICE, ICE PILEUP, ICE OVERRIDE, SEA ICE, SHORES, SHORELINE MODIFICATION, BEACHES, BEAUFORT SEA

BEACHES, BEAUFORT SEA
Recent observations of shore ice pile-up and ride-up along
the coast of the Alaska Beaufort Sea are presented. Information is given to show that sea ice movement on shore
has overridden steep coastal bluffe and has thrust inland
over 150 m, gouging into and pushing up mounds of beach
aand, gravel, boulders and peat and, inland, the tundra material
The resulting ice scar morphology was found to remain
for tens of years. Onshore ice movements up to 20
m are relatively common, but those over 100 m are very
infrequent. Spring is a dangerous time, when sea ice
melts away from the shore, allowing ice to move freely
Under this condition, driving stresses of less than 100 kPa
can push thick sea ice onto the land

RADAR ECHOES, SEASONAL FREEZE THAW, WATER TABLE, SUBSURFACE INVESTIGATIONS, PROFILES, GROUND WATER, SOIL FREEZING, GROUND THAWING.

Investigations of ground radar performance over thawed and seasonally frozen sitis, and sands and gravels containing artificial and natural reflectors were carried out in Alaska. The radar emitted 5-10 ns pulses, the center frequency of which was approximately 150 MHz. The artificial reflectors were metal sheets and discs and the natural reflectors were the groundwater table and interfaces between frozen and thawed material.

CR 93.12 COMPUTER MODELS FOR TWO-DIMEN-SIONAL TRANSIENT HEAT CONDUCTION. Albert, M.R., Apr. 1983, 66p., ADA-134 893, 9 refs. 38-877

HEAT TRANSFER, FREEZE THAW CYCLES, HEAT PIPES, HEATING, MATHEMATICAL MODELS, COMPUTERIZED SIMULATION. PHASE TRANSFORMATIONS.

PHASE TRANSFORMATIONS.

This paper documents the development and verification of two finite difference models that solve the general two-dimensional form of the heat conduction equation, using the alternative-direction insplicit method. Both can handle convective, constant flux, specified temperature and seminfinite boundaries. The conducting medium may be composed of many materials. The first program, ADI, solves for the case where no change of state occurs. ADIPC solves for the case where a freeze/thaw change of phase may occur, using the apparent heat capacity method. Both models are verified by comparison to analytical results

REVIEW OF THE PROPAGATION OF INELAS-TIC PRESSURE WAVES IN SNOW. Albert, D.G., Apr. 1983, 26p., ADA-128 714, 35 refs

SNOW ELASTICITY, EXPLOSIVES, WAVE PROPAGATION, PRESSURE, ELASTIC WAVES,

DETONATION WAVES, TESTS.

DETONATION WAVES, TESTS.

A review on past experimental and theoretical work indicates a need for additional experimentation to characterize the response of snow to inelastic pressure waves. Pressure data from previously conducted explosion tests are analyzed to estimate the elastic limit of snow of 400 kg/cu m density to be about 36 kPs. This pressure corresponds to a scaled distance of 16 m/kg exp 1/3 for charges fired beneath the surface of the snow, and to a scaled distance of 12 m/kg exp 1/3 for charges fired on the air. The effects of a snow cover on the method of clearing a minefield by using an explosive charge fired in the air above the snow surface are aired distance and recommendations are given for further work in this area. Explosive pressure data are used to estimate the maximum effective scaled actions for detonating buried mines at shallow depth to be 0.8 kg exp 1/3. Fuel-air explosive will increase this effective radius significantly because of the increase in the size of the source region. the source region

STUDY ON THE TENSILE STRENGTH OF ICE AS A FUNCTION OF GRAIN SIZE. Currier, J.H., et al., May 1983, 38p., ADA-134 889, 30

Schulson, E.M., St. Lawrence, W.F.

38-2189 ICE CRYSTAL STRUCTURE, TENSILE PROPER-TIES, ICE STRENGTH, ICE CRACKS, GRAIN SIZE, ICE DEFORMATION, COMPRESSIVE PROPERTIES, BRITTLENESS, FRACTURING

An analysis of ice fracture that incorporates dislocation mechanics and linear elastic fracture mechanics is discussed. The derived relationships predict a britle to ductile transition in polycrystalline ice under tension with a Hall-Petch type

dependence of brittle fracture strength on grain size. A uniaxial tensile testing technique, including specimen preparation and loading system design was developed and employed to verify the model. The tensile strength of ice in purely brittle fracture was found to vary with the square root of the recipitical of grain size, supporting the relationship that the theory suggests. The inherent strength of the ice lattice and the Hall-Petch slope are evaluated and findings discussed in relation to previous results. Monitoring of acoustic emissions was incorporated in the tests, providing insights into the process of microfracture during ice deformation.

CR 83-15 LAKE WATER INTAKES UNDER ICING CON-

Dean, A.M., Jr., May 1983, 7p, ADA-128 757, 52 refs.

WATER INTAKES, ICE CONDITIONS, ICE PRE-VENTION, LAKE WATER, ICE MECHANICS, DESIGN CRITERIA, ICING.

An intake may be restricted or clogged by active frazil, passive frazil brash, or a combination of these ice forms. The exact nature of the interactions among the intake structure, the ice and the hydraulic and meteorological conditions that lead to icing problems is extremely site-specific. The better these parameters are quantified, the more tailored and economical the solution A defense against these ice forms may cal the solution A defense against these ice forms may be formulated in four areas the origin of the ice, the transportation mechanics of the ice, the accumulation characteristics of the ice, and the form of the ice when it is in the area of influence of the intake. To produce a lake intake structure that minimizes or climinates icing problems, one may devise an unconstrained or a constrained design. To evaluate solutions to icing problems and/or to supplement incomplete data, a scale-model investigation is recommended. A universal, unconstrained solution would be extremely expensive. incomplete data, a scale-model investigation is fecommended.

A universal, unconstrained solution would be extremely expensive. The more data available through site monitoring and model studies, the better the problem (and therefore the solution) can be bracketed. This paper provides guidance for developing a site-specific solution.

DEVELOPING A MODEL FOR PREDICTING SNOWPACK PARAMETERS AFFECTING VEHI-CLE MOBILITY.

Berger, R.H., May 1983, 26p., ADA-134 878, Refs. p.23-26. 38-878

38-878
SNOW COVER EFFECT. TRAFFICABILITY, VEHICLES, SNOW DEPTH, SNOW DENSITY, VEHICLES, SNOW DEPTH, SNOW DENSITY, SNOW ACCUMULATION, ABLATION, TEMPERATURE EFFECTS, MODELS.

The presence of snow on the ground can impose limitations on the mobility of wheeled and tracked vehicles. Snow depth and density are the two most easily measured snow properties that can be related to mobility over snow Existing models of snowpack accumulation and ablation processes and my fels of internal snowpack structure were examined to determine if a model of the snowpack and be developed for use in predicting the snow parameters that affect mobility Simple models, such as temperature index models, do not provide sufficient snowpack details and the more detailed models required too many measured inputs. Components of the various models were selected from a basis of a snowpack model for predicting snow properties related to mobility model for predicting snow properties related to mobility over snow Methods of obtaining the input data for some components are suggested and areas where more development is needed are described

COMPARISON OF SEA ICE MODEL RESULTS USING THREE DIFFERENT WIND FORCING FIELDS

Tucker, W.B., June 1983, 11p., ADA-134 462, 11 refs. 38-879

ICE MODELS, SEA ICE, WIND PRESSURE, ICE MECHANICS, ATMOSPHERIC PRESSURE, ICE COVER THICKNESS

A sea ice model was applied to the East Greenland Sea to examine a 60-day ice advance period beginning i October 1979. This investigation compares model results using driving geostrophic wind fields derived from three sources winds calculated from sea-level pressures obtained from the National Weather Services operational analysis system resulted in strong selectures concentrated in a narrow band adjacent to the Greenland coast, with moderate selectures elsewhere. The model showed excessive ice transport and thickness build ups in the coastal region. The extreme pressure reduction procedure that was applied to the terrain-following agina coordinate system to obtain sea level pressure. Additional sea level pressure folds were obtained from an independent optimal interpolation unity is that merged EGCE buoys dirifting in the Victic basin with high latitude land stations. A sea ice model was applied to the East Greenland Sea drifting in the Victo basin with high latitude land stations and from manual digitization of the NWS hand-analyzed Sorthern Hemisphere Surface Charts Modeling results using winds derived from both of these fields agreed favorably

DETECTION OF CAVITIES UNDER CON-CRETE PAVEMENT

Kovacs, A., et al, July 1983, 41p., ADA-131 851, 10 refs.

Morey, R.M.

CONCRETE CONCRETE PAVEMENTS, CAVITATION, RADAR ECHOES, DETECTION, CRACKING (FRACTURING), PROFILES.

(FRACTURING), PROFILES.

An evaluation of an impulse radar system for detecting cavities under concrete pavement is discussed, and field results are presented. It was found that a dual antenna mode of surveying was ideal for void detection. In this mode one antenna operated in a transceive mode and a second, offset from the first, operated in a receive-only mode. This arrangement allowed a refraction-type profile survey to be performed, which enabled subpavement voids to be easily detected. Field trails were held at Plattsburgh Air Force Base, where 28 cavities were detected and mapped Drilling of holes verified that a cavity existed and allowed cavity depth to be measured. The cavities varied from 15 in, to 23 in in depth and were up to 20 ft long.

ICE FORCES ON MODEL BRIDGE PIERS. Haynes, F.D., et al, July 1983, 11p., ADA-133 082, 20

refs. Sodhi, D.S., Kato, K., Hirayama, K. 38-395

ICE PRESSURE, ICE LOADS, ICE SOLID INTER-FACE, ICE PUSH, ICE MECHANICS, BRIDGES, PIERS, ICE STRENGTH, MODELS, FLEXURAL STRENGTH, TESTS.

STRENGTH, TESTS.
Small-scale laboratory experiments were conducted on model bridge piers in the CREEL test basin. The experiments were performed by pushing model ice sheets against structures and monitoring the ice forces during the ice/structure interaction. The parameters, varied during the test program, were the geometry of the bridge piers and the velocity, thickness, and flexural strength of the ice. The results are presented in the form of ice forces on sloping and vertical structures with different geometries action on sloping structures, a phenomenon of transition of failure mode from bending to crushing was observed as the ice velocity was steadily increased.

CR 83-20 LAND TREATMENT RESEARCH AND DEVEL-OPMENT PROGRAM: SYNTHESIS OF RE-SEARCH RESULTS.

Wright, E.A.

WASTE TREATMENT, WATER TREATMENT, SANITARY ENGINEERING, LAND RECLAMA-TION, DESIGN CRITERIA, RESEARCH PRO-

The major objective of the Corps of Engineers Land Treatment Research and Development Program was to provide, through research, definitive criteria and procedures to enable the cost-effective and environmentally safe use of land treatment of municipal wastewater

This research included longterm field experiments at different locations within the United States to establish design criteria, laboratory revearch to understand and solve fundamental problems, and evaluation understand and solve fundamental problems, and evaluation of existing land treatment systems to document long-term performance. The information gathered from the land treatment research program has been published in more than 240 technical publications on regional planning, site selection, design procedures, mechanisms of wastewater renovation, site management, site monitoring and environmental effects. During the land treatment program an active technology transfer effort was maintained to transmit research results directly to users. The LTRP clearly demonstrated that land treatment is an attractive alternative to other waste treatment practices. It was also shown that the direct benefits of the program, in terms of increased cost-effectiveness from improved design, were much greater than the program's cost.

CR 83-21 STATISTICAL ASPECTS OF ICE GOUGING ON THE ALASKAN SHELF OF THE BEAUFORT

Weeks, W.F., et al, Sep. 1983, 34p. + map. ADA-134

428, Refs. p 32-34.
Barnes, P.W., Rearic, D.M., Reimnitz, E

TOPOGRAPHY, OFFSHORE DRILLING, OFFSHORE STRUCTURES, SEA ICE, STATISTICAL ANALYSIS, BEAUFORT SEA.

ANALYSIS, BEAUFORT SEA.

The statistical characteristics of ice-produced gouges in the sea floor along a 190-km stretch of the Alaskan coast of the Beaufort Sea between Smith Bay and Camden Bay are studied, based on 1500 km of precision fathometry and side-looking sonar records that were obtained between 1972 and 1979 in water depths to 18 m. The probability density function of the gouge depths into the sediment is represented by a simple negative exponential over four decades of gouge frequency. The deepest gouge observed was 36 m, from a sample of 20,354 gouges that have depths greater than

or equal to 0.2 m. The dominant gouge orientations are usually unimodal and reasonably clustered, with the most frequent alignments roughly parallel to the general trend of the coastline. The value of the mean number of gouges are usually unimodal and reasonably clustered, with the most frequent alignments roughly parallel to the general trend of the coastline The value of the mean number of gouges (deeper than 0.2 m) per kilometer measured normal to the trend of the gouges, varies from 0.2 for protected lagoons to 80 in water between 20 and 38 m deep in unprotected offshore regions. The distribution of the spacings between gouges as measured along a sampling track is a negative exponential. The form of the frequency distribution of the mean number of gouges varies with water depth and is exponential for lagoons and shallow offshore areas, positively skewed for 10 to 20 m depths off the barrier islands, and near-normal for deeper water. As a Poisson distribution gives a reasonable fit to the mean number of gouges distributions for all water depths, it is suggested that gouging can be taken as approximating a Poisson process in both space and time. The distributions of the largest values per kilometer of gouge depths, gouge widths, and heights of the lateral embankments of sediments plowed from the gouges are also investigated. Limited data on gouging rates give an average of 5 gouges per kilometer per year. Examples are given of the application of the data set to hypothetical design problems associated with the production of oil from areas in the Alaskan portion of the Beaufort Sea.

CR 83-22 TRANSPORT OF WATER IN FROZEN SOIL. 1. EXPERIMENTAL DETERMINATION OF SOIL-WATER DIFFUSIVITY UNDER ISOTHERMAL CONDITIONS.

Nakano, Y., et al, Aug. 1983, 8p., ADA-135 419, For another source see 37-4218. 13 refs.
Tice A.R., Oliphant, J.L., Jenkins, T.F.

FROZEN GROUND MECHANICS, SOIL WATER FROZEN GROUND MECHANICS, SOIL WATER MIGRATION, FROST HEAVE, UNFROZEN WATER CONTENT, SOIL MECHANICS, WATER TRANSPORT, ANALYSIS (MATHEMATICS), EXPERIMENTATION.

A new experimental method for measuring the soil-water diffusivity of frozen soil under isothermal conditions is introduced. The theoretical justification of the method is presented and the feasibility of the method is demonstrated by experiments conducted using manne-deposited clay. The measured values of the soil-water diffusivity are found comparable to reported experimental data

STRESS MEASUREMENTS IN ICE. Cox, G.F.N., et al, Aug. 1983, 31p., ADA-133 906, 29

Johnson, J.B.

ICE PHYSICS, STRESSES, LOADS (FORCES), ICE CREEP, ICE ELASTICITY, MEASURING IN-STRUMENTS, ANALYSIS (MATHEMATICS),

TESTS.

The problems associated with measuring stresses in ice are reviewed. Theory and laboratory test results are then presented for a stiff cylindrical sensor made of steel that is designed to measure ice stresses in a biaxial stress field. Loading tests on freshwater and saline ice blocks containing the biaxial ice stress sensor indicate that the sensor has a resolution of 20 kPa and an accuracy of better than 15% under a variety of uniaxial and biaxial loading conditions. Principal stress directions can also be determined within 5 deg. The biaxial ice stress sensor is not significantly affected by variations in the ice elastic modulus, ice creep or differential thermal expansion between the ice and guage. The sensor also has a low temperature sensitivity (5 kPa degC). degC).

CR 83-24 SENSITIVITY OF PLANT COMMUNITIES AND SOIL FLORA TO SEAWATER PRUDHOE BAY, ALASKA.

BRIDGES. PIERS, ICE LOADS, OFFSHORE STRUCTURES, ICE PRESSURE, ICE SOLID IN-TERFACE, COMPRESSIVE PROPERTIES, FLEX-URAL STRENGTH, TESTS.

Ice action on two cylindrical and conical structures, located Ice action on two cylindrical and conical structures, located side by side, has been investigated in a small-scale experimental study to determine the interference effects on the ice forces generated during ice-structure interaction. The proximity of the two structures changes the mode of ice failure, the magnitude and direction of ice forces on the individual structure, and the dominant frequency of ice force variations. Interference effects were determined by comparing the experimental results of tests at different structure spacings.

CR 83-26

MECHANICAL ICE RELEASE PROCESSES. SELF-SHEDDING FROM HIGH-SPEED RO-

Itagaki, K., Oct. 1983, 8p., ADA-135 369, 19 refs.

ICE REMOVAL, PROPELLERS, ICING, ICE AC-CRETION, SUPERCOOLED FOG, ICE FORMA-TION, ICE ADHESION, ICE STRENGTH, ICE CONTROL, TENSILE PROPERTIES, ANALYSIS (MATHEMATICS).

(MATHEMATICS).

Ice accreted on high-speed rotors operating in supercooled fog can be thrown off by centrifugal force, creating severe unbalance and dangerous projectiles. A simple force balance analysis indicates that the strength of accreted ice and its adhesive strength can be obtained by measuring the thickness of the accretion, the location of the separation, the rotor speed and the density. Such an analysis was applied to field and laboratory observations of self-shedding events. The results agree reasonably well with other observations.

DRIVING TRACTION ON ICE WITH ALL-SEA-SON AND MUD-AND-SNOW RADIAL TIRES. Blaisdell, G.L., Nov. 1983, 22p., ADA-136 115, 9 refs. 38-2555

RUBBER ICE FRICTION, TRACTION, TIRES, RUBBER SNOW FRICTION, ICE TEMPERATURE, ADHESION, DESIGN.

This study reports on a companson of the driving traction performance on ice of a selected group of all-season radial tires with mud-and-snow radial tires in addition to performance variation due to tread design, the effects of tire inflation ance variation due to tread design, the effects of tire inflation pressure and ice temperature are explored. The results indicate that no significant tractive advantage on ice can be attributed to tread design. The contribution of tire tread to traction on ice is completely overshadowed by adhesion between the ice and the compound which makes up the tire's contact surface. Based on adhesion, a slight favoring of all-season tires is found. Increasing ice temperature generally decreased the tractive capability of a specific tire. For several tires, however, the opposite was true. Reduced inflation pressure also caused a slight decrease in the tractive performance parameters calculated.

LONG-TERM PLANT PERSISTENCE AND RES-TORATION OF ACIDIC DREDGE SOILS WITH SEWAGE SLUDGE AND LIME. Palazzo, A.J., Dec. 1983, 11p., ADA-137 451, 31 refs.

DREDGING, SOIL CHEMISTRY, SEWAGE TREATMENT, REVEGETATION, LIMING, SLUDGES, LAND RECLAMATION, GRASSES.

SLUDGES, LAND RECLAMATION, GRASSES. A field study was conducted to determine whether sewage studge and lime could be useful as soil amendments on acidic (pH 2 4) and infertile dredged spoils and to evaluate grasses that may be suitable for restoring acidic dredged spoils. Applications of dolomitic limestone in combination with sewage sludge or commercial fertilizer and topsoil improved soil fertility and produced a better overall growth environment at the site. Metal concentrations resulting from sludge applications increased but not to excessive levels. Movement of metals below the 20-cm depth was noted for the extractible forms of zinc, copper and nickel. A total of 29 grass treatments, containing grasses seeded alone or in combinations and receiving the sludge/lime treatment, were evaluated over a seven-year period, and selected grasses were analyzed for mineral composition. All grass species showed good establishment on the amended acidic spoil.

CR 83-29 EROSION PERENNIALLY FROZEN OF STREAMBANKS.

Lawson, D.E., Dec. 1983, 22p., ADA-138 410, Refs. 38.4466

SHORE EROSION, PERMAFROST THERMAL PROPERTIES, BANKS (WATERWAYS), FROZEN GROUND STRENGTH, SOIL EROSION, STABILITY, GULLIES, SHORELINE MODIFICATION, STREAMS, TEMPERATURE EFFECTS,

HYDRAULICS

A literature review indicated that the effects of permafrost on streambank erodibility and stability are not yet understood because systematic and quantitative measurements are seriously lacking Consequently, general controversy exists as to whether perennially frozen ground inhibits lateral erosion and bankline recession, or whether it increases bank recession rates. Perennially frozen streambanks erode because of rates. Perennially frozen streambanks erode because of modification of the bank's thermal regime by exposure to air and water, and because of various erosional processes. Factors that determine rates and locations of erosion include physical, thermal and structural properties of bank sediments, stream hydraulics and climate Thermal and physical modification of streambanks may also induce accelerated erosion within permafrost terrain removed from the immediate river environment. Bankline or bluffline recession rates are highly usualshly examine from less than 1 m/sept to over 30 m/sept. environment. Bankine or bluttline recession rates are highly variable, ranging from less than 1 m/year to over 30 m/year and, exceptionally, to over 60 m/year. Long-term observations of the physical and thermal crosion processes and systematic ground surveys and measurements of bankline-bluffline recession rates are needed

ICE SHEET RETENTION STRUCTURES Perham, R.E., Dec. 1983, 33p., ADA-138 030, Refs.

ICE CONTROL, ICE BOOMS, STABILIZATION. ICE SHEETS, ICE COVER, FRAZIL ICE.

Ice sheets are formed and retained in several ways in nature, and an understanding of these factors is needed before most and an understanding of these factors is needed before most structures can be successfully applied. Many ice sheet retention structures float and are somewhat flexible; others are fixed and rapid or semirigid. An example of the former is the Lake Erie ice boom and of the latter, the Montreal ice control structure. Ice sheet retention technology is changing. The use of timber cribs is gradually but not totally gaving way to sheet steel pillings and concrete cells. New structures and applications are being tried but with caution. Ice-hydraulic analyses are helpful in predicting the effects of structures and channel modifications on ice cover formation and retention. Often, varying the flow rate in a raticular system at the proper time. on ice cover formation and retention. Often, varying the flow rate in a particular system at the proper time will make the difference between whether a structure will or will not retain ice. The structure, however, invariably adds reliability to the sheet ice retention process

CR 83-31 MECHANICS OF ICE JAM FORMATION IN

Ackermann, N.L., et al, Dec. 1983, 14p., ADA-138 371, For another version see 36-3281. 12 refs.

ICE JAMS, ICE FORMATION, ICE MECHANICS. RIVER ICE, RIVER FLOW, HYDRAULICS, ICE CROSSINGS, COMPUTER PROGRAMS, MATH-EMATICAL MODELS.

A mathematical model is described that is used to determine A mathematical model is described that is used to determine the maximum ice conveyance capacity of a river channel. Based upon this model, computer programs were developed that enable the ice discharge to be calculated for steady-state flow conditions. For rivers that have uniform flow, the maximum ice-conveying capacity can be described with a simple function expressed in terms of the size of the ice fragments, channel geometry, and the flow of water in the river. For nonuniform flows, the computer program determines the elevation profile of the surface larger in addition in the fiver For nonuniform flows, the computer program determines the elevation profile of the surface layer in addition to other flow characteristics, such as the velocity and surface concentration of the ice fragments. The location along this surface profile where the ice conveyance capacity becomes less than the upstream supply is determined and is considered to be the position where a surface ice jam or ice bridge will be formed.

CR 83-32 ICE FORCE MEASUREMENTS ON A BRIDGE PIER IN THE OTTAUQUECHEE RIVER, VER-MONT.

Sodhi, D.S., et al, Dec. 1983, 6p., ADA-139 425, 2

Kato, K., Haynes, F.D.

ICE LOADS, ICE FLOES, PIERS, BRIDGES, ICE PRESSURE, RIVER ICE, WATER LEVEL, ICE STRENGTH, ICE MECHANICS.

lce forces on a bridge pier in the Ottauquechee River, in Quechee, Vermont, were measured by installing four panels—each capable of measuring forces in the normal and tangential direction—on both sides of a vertical V-shaped pier nose The measured forces are presented for a short period during an ice run. After the ice run, the thickness and sizes

of the ice floes were measured and the compressive strength of the ice was determined in the laboratory from the ice samples collected along the river banks. The water level measurements made at several locations along the river are also presented for the period of the ice run.

CR 83-33
THERMODYNAMIC MODEL OF CREEP AT
CONSTANT STRESSES AND CONSTANT
STRAIN RATES.

Fish, A.M., Dec. 1983, 18p., ADA-139 883, Refs. p.16-18. 38-4470

SOIL CREEP, FROZEN GROUND THERMODY-NAMICS, FROZEN GROUND MECHANICS, ICE MECHANICS, STRESSES, STRAINS, RHEOLO-GY, MATHEMATICAL MODELS.

MECHANICS, STRESSES, STREINS, KIEGLO-GY, MATHEMATICAL MODELS.

A thermodynamic model has been developed that for the first time describes the entire creep process, including primary, secondary, and tertuary creep, and failure for both constant streas (CS) tests and constant strain rate (CSR) tests, in the form of a unified constitutive equation and unified failure criteris. Deformation and failure are considered as a single thermoactivated process in which the dominant role belongs to the change of entropy. Failure occurs when the entropy change is zero. At the moment the strain rates in CS tests reach the minima and stress in CSR tests reaches the maximum (peak) values Families of creep and stress-strain curves, obtained from uniaxial compression CS and CSR tests of frozen soil, respectively (both presented in dimensionless coordinates), are plotted as straight lines and are superposed, confirming the unity of the deformation and failure process and the validity of the model. A method is developed for determining the parameters of the model, so that creep deformation and the stress-strain relationship of ductile materials such as soils can be predicted based upon information obtained from either type of test

TOWARD IN-SITU BUILDING R-VALUE MEASUREMENT.

Flanders, S.N., et al, Jan. 1984, 13p., ADA-139 917,

Marshall, S.I.

THERMAL CONDUCTIVITY, BUILDINGS, THERMAL INSULATION, WALLS, HEAT FLUX, TEMPERATURE MEASUREMENT, INFRARED PHOTOGRAPHY, ACCURACY.

PHOTOGRAPHY, ACCURACY.

A technique for measuring the thermal resistance (R-value) of large areas of building envelope is under development it employs infrared thermography to locate radiant temperature extremes on a building surface and to provide a map of normalized temperature values for interpolation between locations. Contact thermal sensors (thermocouples for temperature and thermopiles for heat flow) are used to calculate the R-value at specific locations by summing the output from each sensor until the ratio between temperature difference from inside to outside surface and heat flow converges to a constant value. R-value measurements of a wood frame insulated wall were within 13% of the expected theoretical value. Similar measurements of a masonry wall were 31 and 43% less than expected. Experimentation demonstrated that a large ratio between temperature difference was the single most important variable affecting accuracy and speed of convergence. Thermal guards around heat flow sensors were of little value, according to both experimentation and computer simulation. Attempts to match the absorptivity of sensors with their surroundings may have been insufficient to diminish about 10% of the remaining error in measurement to diminish about 10% of the remaining error in measurement to the standard of the convection of the problems for accuracy in the masonry construction. Currently, an investigator cannot rely on the literature for guidance massessing the limitations on accuracy for in-situ building R-value measurement. R-value measurement.

ELECTROMAGNETIC PROPERTIES OF SEA ICE.

Morey, R.M., et al. Jan. 1984, 32p., ADA-140 330, 26

Kovacs, A. Cox. G.F.N

ICE ELECTRICAL PROPERTIES, SEA ICE, ELECTROMAGNETIC PROPERTIES, DIELECTRIC PROPERTIES, ELECTRICAL RESISTIVITY, ICE SPECTROSCOPY, ICE CRYSTAL STRUCTURE, ANISOTROPY, BRINES

IURE, AMISOTROFT, DRIVED.

Investigations of the in situ complex dielectric constant of sea ice were made using time-domain spectroscopy. It was found that (1) for sea ice with a preferred horizontal crystal e-axis alignment, the anisotropy or polarizing properties of the ice increased with depth, (2) brine inclusion conductivity increased with decreasing temperature down to about -8. of the see increased with depth, (2) brine inclusion conductivity increased with decreasing temperature down to about -8. C, at which point the conductivity decreased with decreasing temperature. (3) the DC conductivity of sea ice increased with increasing brine volume. (4) the real part of the complex dielectric constant is strongly dependent upon brine volume but less dependent upon the brine inclusion orientation. (5) the imaginary part of the complex dielectric constant was strongly dependent upon brine inclusion orientation but much less dependent upon brine volume. Because the electromagnetic (EM) properties of sea ice are dependent upon the physical state of the ice, which is continually changing.

it appears that only trends in the relations ps between the EM properties of natural sea ice and its bine volume and brine inclusion microstructure can be established.

CR 84-03 MODEL TESTS ON TWO MODELS OF WTGB 140-POOT ICEBREAKER.

Tatinclaux, J.C., Jan. 1984, 17p., ADA-139 882, 10

ICEBREAKERS, ICE COVER STRENGTH, ICE CONDITIONS, ICE BREAKING, UREA, DOPED ICE, MODELS,

ICE, MODELS.

The results of resistance tests in level to, and broken ice channels are presented for two model, of the WTGB 140-ft tecbreaker at scales of 1 10 and 1 24, respectively. No scale effect on the resistance in level toe could be detected between the two models. From the test results an empirical predictor equation for the full scale toe resistance is derived. Predicted resistance is compared against, and found to be 25 to 40% larger than, available full-scale values estimated from thrust measurements during full-scale trials of the Great Lakes techreaker Katmas Bay.

CR 84-04 EFFECTIVENESS AND INFLUENCES OF THE NAVIGATION ICE BOOMS ON THE ST. MARYS

Perham, R.E., Jan 1984, 12p., ADA-139 908, 8 refs.

ICE NAVIGATION, ICE BOOMS, RIVER ICE, ICE BREAKING, ICE CONTROL, ICE BREAKUP, ICE MECHANICS, ICE COVER THICKNESS.

ICE BREAKING, ICE CONTROL, ICE BREAKUP, ICE MECHANICS, ICE COVER THICKNESS.

Ice problems developed in the Sault Ste. Marie, Michigan, portion of the St. Marys River because of winter navigation. Passing ships and natural influences moved ice from Soo Harbor into Little Rapids Cut in sufficient quantities to siam, cause high water in the harbor, and prevent further ship passage. After physical model and engineering studies, two ice booms with a total span of 1375 ft (419 m) with a 250-ft (76-m) navigation opening between were installed at the head of Little Rapids Cut in 1975 A modest field study program on the booms was conducted for the ensuing four winters to determine ice and boom interaction and the effects of ship passages on the system. Forces on some anchors were recorded and supplemental data were taken by local personnel. Several reports have been written about the booms' early operations. This paper presents a four-year summary of the main effects of the boom on ice and ship interaction and vice versa. Throughout the four winter seasons, the small quantities of ice lost over and between the booms were manageable. Ships usually passed through the boom without influencing the boom force levels, but at times they brought about large changes. One boom needed strengthening, and artificial islands were added for upstream ice stability. Coast Guard icebreakers were also a necessary part of winter navigation in this area.

CR 84-05 MORPHOLOGY AND ECOLOGY OF DIATOMS IN SEA ICE FROM THE WEDDELL SEA Clarke, D.B., et al, Feb. 1984, 41p., ADA-141 994,

ICE COMPOSITION, ALGAE, PACK ICE, SEA ICE, PLANKTON, ICE CORES, ICE COVER THICKNESS, ICE SALINITY, ECOLOGY, CLASSIFICATIONS, ANTARCTICA—WEDDELL SEA. SIFICATIONS, ANTARCTICA—WEDDELL SEA.
Diatom species composition and relative abundances were
determined for tee cores obtained from Weddell Sea pack
tice during the October-November 1981 Weddell Polynya
expedition (WEPOLEX) lee thickness and salinity indicate
that the ice was less than one year old. The predominant
tice type (70%) was frazil, which has the capacity to mechanically incorporate biological material through nucleation and
scavenging. Diatoms were found throughout the length
of the cores. Species showed down-core fluctuations in
abundance that appeared to be correlated with changes in
tice type. Pennate forms were more abundant than centrics,
the average ratio being 16.1 Diatom frustules with intact
organic material were more abundant (50 million cells/liter).
Differences in species abundances are attributed initially to
incorporation of algal cells from a temporally changing water
column and subsequently to diatom reproduction within the
ties. Scanning electron micrographs illustrating the morphologic characteristics of the predominant species are included.

CR 84-06

CR 84-06 AEROSOL GROWTH IN A COLD ENVIRON-

Yen, Y-C., Feb 1984, 21p., ADA-139 907, 4 refs.

AEROSOLS, GROWTH, HEAT TRANSFER, MASS TRANSFER, VAPOR DIFFUSION, COLD WEATHER TESTS, ANALYSIS (MATHEMATICS), DROPS (LIQUIDS), TEMPERATURE EF-

An expression relating acrosol growth to cold environmental An expression relating acrossol grown to cold environmental conditions was developed. This was accomplished by solving the diffusion equation with the method of Laplace transformation. The series solution was expressed in terms of the ratio of vapor deneity over displict surface to droplet density, ratio of environmental vapor density at time zero to vapor density over droplet surface, and ratio of product of diffusion coefficient and time to square of initial radius of condensation nucleus. To take into account the variation of the vapor density over the surface of an acidic condensation nucleus due to the continuous dilution of the droplet, the solution was obtained by assuming various levels of constant vapor

CR 84-07 FORCE DISTRIBUTION IN A FRAGMENTED ICE COVER.

EXPERIMENTATION.

Experiments were conducted in CRREL's refingerated flume facility to examine the two-dimensional force distribution of a floating, fragmented ice cover restrained by a boom in a simulated river channel. To determine the force distribution, a vertically walled channel, instrumented for measuring normal and tangential forces, and an instrumented restraining boom were installed in a 400-by 1.3-m flume Two sizes of polyetylene blocks and two similar sizes of freshwater ice blocks were tested using water velocities ranging from 10 to 30 cm/s. The forces measured at the instrumented boom leveled off with increasing cover length. The contribution of the increasing shear forces developed along the shorelines to this leveling off in the data was clearly evident. The shear coefficients of the polyethylene blocks averaged 0.43, and the freshwater ice averaged 0.044. The normal force measured along the instrumented shortline could not be related simply by a K coefficient to the longitudinal force; another expression was required, with a term being a function of the cover thickness and independent of the undercover shear stress or cover length. By adding this term, good agreement was then found between the measured and predicted values of the boom forces and the shoreline normal and shear forces

CR 84-08 MECHANICAL PROPERTIES ('F MULTI-YEAR SEA ICE. TESTING TECHNIQUES.

ICE MECHANICS, SEA ICE, PRESSURE RIDGES, ICE STRENGTH, COMPRESSIVE PROPERTIES, TENSILE PROPERTIES, STATIC LOADS, ICE PHYSICS, ICE SAMPLING, ICE FLOES, STATISTICAL ANALYSIS.

This report presents the results of the first phase of a test program designed to obtain a con prehensive understanding of the mechanical properties of multi-year sea ice from the Alaskan Beaufort Sea In Phase I, 222 constant-train-rate uniaxial compression tests were performed on ice samples rate uniaxual compression tests were performed on ice samples from ten multi-year pressure ridges to examine the magnitude and variation of ice strength within and between pressure ridges. A limited number of constant-istrain-rate compression and tension tests, constant-load compression tests, and conventional triaxual tests were also performed on ice samples from a multi-year flot to provide preliminary data for developing ice yield unteria and constitutive laws for multi-year sea ice. Data are presented on the strength fultire strain sea ice. Data are presented on the strength, failure strain, and modulus of multi-year sea ice under different loading conditions. The statistical variation of ice strength within conditions. The statistical variation of ice strength within and between pressure ridges is examined, as well as the effects of the temperature, porosity, structure strain rate and confining pressure on the mechanical properties of multiCR 84-10

MODELING TWO-DIMENSIONAL FREEZING USING TRANSFINITE MAPPINGS AND A MOVING-MESH FINITE ELEMENT TECH-NIQUE.

Albert, M.R., May 1984, 45p., ADA-144 131, 29 refs.

FREEZING, PHASE TRANSFORMATIONS, HEAT TRANSFER, BOUNDARY VALUE PROB-LEMS, MATHEMATICAL MODELS, LATENT HEAT.

Freezing phase change problems in conduction heat transfer represent a set of me ing boundary problems for which much interest currently "xists". In the work presented here, two-dimensional freezing is modeled by incorporating the use of transfinite mappings with a moving-mesh finite element technique. The use of transfinite mapping in governing interior mesh motion is shown to provide very acceptable results and is demonstrated to be the most efficient. acceptable results and is demonstrated to be the most efficient general computational technique used to date. The model developed is capable of using either Cartesian or (r,z) cylindrical coordinates. Both frozen and unfrozen phases may be modeled when conduction governs behavior in both In the case of freezing of a fluid as it flows through a pipe the usefulness of always having the phase boundary coincident with element boundaries is demonstrated. Results of the with element boundaries is demonstrated. Results of the model are shown to compare well with analytical and experimental results. A von Neumann stability analysis is performed for the numerical solution and tends to support the observation that the occurrence of a high Peclet number in the moving-mesh model of heat conduction may produce distortions of the numerical solution

CD 84-11 SEA ICE DATA BUOYS IN THE WEDDELL SEA. Ackley, S.F., et al, May 1984, 18p, ADA-144 953, 6

Holt, ET.

ATMOSPHERIC PRESSURE, AIR TEMPERA-TURE, ANTARCTICA—WEDDELL SEA.

Data obtained from two sets of data buoys either air-dropped or deployed by ship onto the Weddell Sea pack ice during the period from Dec 1978 to Nov 1980 are presented. The buoy data include position, pressure and temperature information and to date represent the most complete combined weather and pack ice drift records for the ice-covered southern ocean regions. The buoys tended to drift north initially and then to turn cast generally between latitudes 62 S and 64 S. Buoy 1433 turned east farther south at approximately 67 S but at about the same time as buoy 0527, implying that the westerly wind belt was farther south than usual in 1979. The range of air pressures—from about 950 mb to about 1020 mb—is typical of the circumpolar low pressure trough in the Southern Hemisphere. All buoys were equipped with an internal or compartment temperature sensor. The buoys also contained an external air temperature sensor in a ventilated, shielded can at 1-m height. Although differences of 10 C or more between recorded air and compartment temperatures are higher probably because the buoy is radiationally heaved. We found that subtracting 3 C from the average daily compartment temperature yielded a good estimate of the average were temperature yielded a good estimate of the average air temperature for any given day. This technique can be used to construct average daily air temperature records for the 1979 buoys which only contained the internal or compartment temperature sensor.

ICING RATE ON STATIONARY STRUCTURES UNDER MARINE CONDITIONS.

Itagaki, K., June 1984, 9p., ADA-145 797, 7 refs 39-385

ICING, OFFSHORE STRUCTURES, ICE FORMA-TION, OFFSHORE DRILLING, SHIP ICING, SEA SPRAY, WIND VELOCITY, ANALYSIS (MATH-EMATICS).

The rate of ice accumulation on stationary structures was calculated using published data. The results were compared with icing measured on board ships. Although the general trend of this calculation indicated parallelism with the onboard measurements, the measured ice accumulation rate on ships needed a 5 to 8 m/s higher windspeed to correspond with the calculated rate for stationary structures

NITROGEN REMOVAL IN WASTEWATER PONDS.

Reed, S.C., June 1984, 26p., ADA-144 971, 26 refs

39-386
WASTE TREATMENT, ICE COVER EFFECT.
WATER TREATMENT, SANITARY ENGINEER-ING. PONDS, CHEMICAL ANALYSIS, MATH-EMATICAL MODELS

EMATICAL MODIFIES

Nittogen removal from wastewater can be required in a number of situations, and many military facilities have been or will be retrofitted for this purpose. Treatment lagoons and holding or storage ponds are a common treatment method or a common component in many systems. Qualitative observations over several decades document nitrogen losses.

from these systems due to a variety of possible biochemical interactions. This analysis is based on an extensive body of quantitative data recently published by the U.S. EPA. A mathematical model was developed and validated that indicated that nitrogen removal from pond systems is dependent on pH, temperature, and detention time. The specific biochemical factors could not be isolated, but the analysis suggests that volatilization of ammonia is the major pathway for nitrogen loss. The model can be used as a design equation for new facilities, for retrofits, and for land treatment systems with storage ponds, since nitrogen is a critical design parameter in these cases.

CR 84-14 EFFECTS OF LOW TEMPERATURES ON THE GROWTH AND UNFROZEN WATER CONTENT OF AN AQUATIC PLANT.

Palazzo, A.J., et al, June 1984, 8p., ADA-147 107, 24

Tice, A.R., Oliphant, J.L., Graham, J.M.

PLANT TISSUES, TEMPERATURE EFFECTS, UNFROZEN WATER CONTENT, COLD TULER-ANCE, LOW TEMPERATURE TESTS, G. OWTH, DAMAGE, NUCLEAR MAGNETIC NANCE, AQUATIC PLANTS.

DAMAGE, NUCLEAR MAGNETIC RESONANCE, AQUATIC PLANTS.

Two laboratory studies were performed to investigate the effects of low temperatures on the aquatic plant Ceratophyllum dimersum L. Whole plants were subjected to low-temperature treatments of +4.0 and -6C for 48 hours, and regrowth was compared to an untreated control. The control and +4C-treated plants gained weight, while visible injury and reductions in plant biomass were noted 30 days after treatment at the two lower temperatures. The -6C treatment killed the plants, while the 0C treatment injured them to some degree in another phase of this study, nuclear magnetic resonance (NMR) analysis of plant buds, leaves and stems showed that lowering temperatures caused the plants' unifrozen water content to drop rapidly as the temperature approached -5C, then slowly as temperatures sporoached -13C. From -13C to -22C there was little change in unfrozen water content. The results show that ice in this plant causes injury that affects subsequent regrowth; temperatures of -6C or below can actually kill them This killing temperature was also near the point where frozen water content increased only slightly with lower temperatures. NMR analysis could be one way of determining plant tolerance to cold. It appears from this study that this weedy species is susceptible to low-temperature injury, and subjecting this plant to cold may be a promising method of weed control in northern lakes.

CR 84-15 BASELINE ACIDITY OF ANCIENT PRECIPITA-TION FROM THE SOUTH POLE

Cragin, J.H., et al, June 1984, 7p, ADA-145 007, 33

Giovinetto, M.B., Gow, A.J. 39-387

ICE COMPOSITION, ICE CORES, DRILL CORE ANALYSIS, PRECIPITATION (METEOROLO-GY), CHEMICAL PROPERTIES, FIRN, PALEO-CLIMATOLOGY, ANTARCTICA—AMUNDS-EN-SCOTT STATION.

Measurements of meliwater pH from annual layers of South Pole firn and ice samples ranging in age from 40 to 2000 years BP show that precipitation at this remote site has a higher natural acidity than that expected from atmospheric equilibrium with CO2 The average pH of desertated (CO2a higher natural aendity than that expected from atmospheric equilibrium with CO2. The average pH of deaerated (CO2-free) samples was 5 64, while air-equilibrated samples averaged 5 37, a pH that is about a factor of two more acidic than the expected background pH of 5 65.

The observed "excess" acidity can be accounted for by natural SO4 and NO3 ion levels in the samples probably originating from non-anthropogenic H2SO4 and HNO3. Because of the presence of these naturally occurring acids in South Pole precipitation, a pH of 5 4 is considered a more representative baseline reference pH for acid precipitation studies.

CR 84-16 EFFECTS OF SOLUBLE SALTS ON THE UN-FROZEN WATER CONTENTS OF THE LANZ-HOU, P.R.C., SILT. Tice, AR, et al, June 1984, 18p, ADA-152 825, 24

Zhu, Y. Oliphant, J.L. 39-2916

UNFROZEN WATER CONTENT, SALINE SOILS, LOESS, SOIL WATER, SOLUBILITY, TEMPERATURE EFFECTS, ELECTRICAL RESISTIVITY

RESISTIVITY

Phase composition curves are presented for a typical saline silt from Lanzhou, P.R.C., and compared to some s.lts from Alaska. The unfrozen water content of the Chinese silt is much higher than that of the Alaskan wits due to the large amount of soluble salits present in the silts from China, which are not present in silt from interior Alaska. When the salt is removed, the unfrozen water content is then similar for both the Chinese and Alaskan silt. Here, we introduce a technique for correcting the unfrozen water content of partially fiven soils due to high salt concentrations. We calculate the equivalent molality of the salts in the unfrozen water at various temperatures from a measurement of the clevincal ecoductivity of the extract from saturated parte.

CR 84-17

PULSE TRANSMISSION THROUGH PROZEN

Arcone, S.A., July 1984, 9p., ADA-147 108, 19 refs

FROZEN GROUND PHYSICS, RADIO WAVES, WAVE PROPAGATION, PERMAFROST PHYSICS, RADAR, TEMPFRATURE EFFECTS.

SICS, RADAR, TEMPFRATURE EFFECTS.
VHF-band radiowave short pulses were transmitted within the permafrost tunnt at Fox, Alaska, over distances between 2.2 and 10.5 m. The propagation medium was a frozen silt containing both disseminated and massive ice with temperatures varying from -7C near the transmitter to probably -2C near the center of the tunnel overburden pulses underwent practically no dispersion in the coldest zones but did disperse and refract through the warmer overburden, as suggested by calculations of the effective dielectric constant. Most significantly the measured frequency content decreased as the effective dielectric constant increased. The results indicate that deep, cross-borchole pulse transmissions over distances greater than 10 m might be possible, especially when the ground is no warmer than -4C. The information thus gained could be used for identifying major subsurface variations, including ground ice features.

FRAZIL ICE FORMATION.

Ettema, R., et al, July 1984, 44p., ADA-147 425, 34

Karim, M.F., Kennedy, J.F.

FRAZIL ICE, ICE FORMATION, HEAT FRANSFER, PARTICLE SIZE DISTRIBUTION MATHEMATICAL MODELS, TESTS, TUBULENT FLOW, WATER TEMPERATURE, COMPUTER PROGRAMS, SUPERCOOLING.

PROGRAMS, SUPERCOOLING.
This report investigates the influences of turbulence and water temperature on frazil ice formation
the quantity of frazil ice formed in a specified volume of supercooled water increasing water temperature of turbulence intensity on the rate of frazil ice formation, however, is more pronounced for larger initial supercooling. The turbulence characteristics of a flow affect the rate of frazil ice formation by governing the temperature to which the flow can be supercooled by influencing heat transfer from the frazil ice to surrounding water, and by promoting collision nucleation, particle and floc rupture and increasing the number of nucleation sites

Larger frazil ice particles collision nucleation, particle and floc rupture and increasing the number of nucleation sites. Larger frazil ice particles formed in water supercooled to lower temperatures. The particles usually were disks, with diameters several orders greater than their thickness. Particle size generally decreased with increasing turbulence intensity. This report develops an analytical model, in which the ice formation is related to temperature rise of a turbulent volume of water from the release of latent heat of fusion of liquid water to ice. Experiments conducted in a turbulence jar with a heated, vertically oscillating grid served both to guide and to calibrate the analytical model as well sate afford insights into frazil ice formation. The formation of frazil ice was studied for temperatures of supercooled water ranging from -0.9 to -0.05 C

FORECASTING WATER TEMPERATURE DE-CLINE AND FREEZE-UP IN RIVERS.

Shen, H.T, et al, July 1984, 17p, ADA-147 068, 14 refs

Foltyn, E.P. Daly, S.F.

ICE FORMATION, RIVER ICE. WATER TEM-PERATURE, FREEZEUP, LONG RANGE FORE-CASTING, COMPUTER PROGRAMS

In this study a method for making long-range forecasts of freeze-up dates in rivers is developed. The method requires the initial water temperature at an upstream station. requires the initial water temperature at an upstream station, the long-range art temperature forecast, the predicted mean flow velocity in the river reach, and water temperature response parameters. The water temperature response parameters can be either estimated from the surface heat exchange coefficient and the average flow depth or determined empirically from recorded air and water temperature data. The method is applied to the St. Lawrence River between Kingston, Ontario, and Massena. New York, and is shown to be capable of accurately foresting forecast. of accurately forecasting freeze-up

CR 84-20 CHANGE IN ORIENTATION OF ARTILLERY-DELIVERED ANTI-TANK MINES IN SNOW. Bigl, S.R., Aug 1984. 20p., ADA-090 946, 5 refs.

MILITARY OPERATION, TANKS (COMBAT VEHICLES), SNOW COVER EFFECT, ORIENTA-TION, TEMPERATURE EFFECTS, TESTS.

TION, TEMPERATURE EFFECTS, TESTS.
The Remote Anti Armor Mine System (RAAMS) employs scatterable mines that are delivered by ejection from a projectife during flight. A problem with delivery of RAAMS mines in anow arises because a percentage of them are equipped with an anti-disturbance mechanism. The natural disturbance or tilling of the mines while melting into the smooth on a warm or sunny day may cause them to detonate Five tests lasting 3 hours to 5 days were conducted at CRREL to study change in orientation of RAAMS mines after landing in snow. Mines were set in the snow at

various repose angles and their operatations were recorded periodically. The tests indicated that a critical angle of approximately 65 deg from horizor all divides the settlement patterns of the mines. Those with initial repose angles below 65 deg will tend towards 5 deg, while more steeply dipping mines will most often come to rest fin a vertical position. Angular change rates during midday hours (0900–1500) ranged from 0 deg to 10 deg (er hour. On sunny days with near-freezing temperaturing, most mines had a total oite-day change of 10 deg to 2 deg. From these tests, it appears that many of the mines would have detonated if they had been equipped with an anti-disturbance mechanism.

CR 84-21 IMPACT OF DREDGING ON WATER QUALITY AT KEWAUNEE HARBOR, WISCONSIN. Iskandar, I.K., et al, Aug. 1984, 16p., ADA-148 321,

Cragin, J.H., Parker, L.V., Jenkins, T.F 40-3546

DREDGING, SEDIMENTS, WASTE DISPOSAL, WATER POLLUTION, LACUSTRINE DEPOSITS, WATER CHEMISTRY, PORTS, UNITED STATES WISCONSIN-KEWAUNEE.

Six sediments and four water samples were collected from Kewaunee, Wisconsin. in 1981, prior to dredging of this Lake Michigan harbor. A modified clutrate test was used Kewainee, Wisconsin, in 1981, pror to dredging of this Lake Michigan harbor. A modified clutrate test was used to estimate potential impact on water quality upon harbor dredging and disposal of the sediments in a confined facility. The modification of the test included a comparison between containment release under aerated vs unaerated conditions and filtered vs unfiltered clutrates. Statistical analysis showed that the differences in the chemical characteristics between the filtered and unfiltered samples were significant for soluble reactive P and all the tested metals except Cu Significant but low amounts of heavy metals (Cd. Pb. Zn. Ni, Fe. Mn) and soluble reartive P will be released to the water if the effluent is not filtered. Under aerated conditions, COD in both the filtered and unfiltered samples was higher than under unaerated conditions. In contrast, total organic carbon was much higher under the unaerated condition than under aerated conditions. The study concluded that sediment and containmant releases from the confined disposal facility (CDF) to the harbor water were less than those from the Kewainer River input. Also, retention of effluent in the CDF for about four days decreased the suspended solids in the effluent to about 40 to 50 mg/L, which is similar to the concentration in the lake water. The use of sand filters should not be for routine operation but rather for emergency cases when there is not enough time for effluent retention in this CDF.

CR 84-22 REGIONAL AND SEASONAL VARIATIONS IN SNOW-COVER DENSITY IN THE U.S.S.R. Bilello, M.A., Aug. 1984, 70p, ADA-148 429, Refs.

CANOPY, MAPPING, USSR.
Regional and seasonal variations in snow-cover density (SCD) in the USSR were determined through the analysis of data obtained from all available Soviet literature. A relationship found between observed winter wind speeds and SCD values recorded from November through March made it possible to develop a snow-density map of the USSR. The map was divided into five general categories of SCD, ranging from values less than or equal to 0.21 g/cu cm at interior stations with very light winds to values greater than or equal to 0.31 g/cu cm at artic locations with strong winds. Since this literature survey indicated that the reported Soviet SCD values were incorrect due to instrumental errors, adjustments to the data in this study were required. Month-to-month investigation of the SCD data revealed a gradual increase in density from November to March and that the SCD values under forest canopies averaged from 4 to 14% lower than those recorded in open areas Also included in this report are 1) a compilation of pertinent passages in the Soviet literature on SCD. 2) a map showing the location of SCD measurements, and 3) an average winter wind speed chart for the USSR.

CR 84-23 EFFECT OF SNOW ON VEHICLE-GENERATED SEISMIC SIGNATURES

Albert, D G, Aug 1984, 24P, ADB-090 976, 10 refs.

MILITARY OPERATION, SNOW COVER EF-FECT. SEISMOLOGY, DETECTION, VEHICLES, ATTENUATION, ACOUSTICS. SEASONAL VARIATIONS.

Vehicle-generated sessingiams recorded under summer and uniter conditions at Fort Devens. Massachusetts, are analyzed and compared. The data were recorded using three-component geophones located just beneath the ground surface and microphones mounted on tripods 0.3 in tall. Winter data were recorded when a 0.7-m thick snow cover was present. The filtering effect of this snow cover on the seismic data was striking. The appearance and frequency content of the recorded ground motion changed dramatically from summer to winter because snow attenuates the acoustic-to-seismic coupled energy. These changes were verified by magnitude-squared coherence analysis and by a simple Wiener prediction. Vehicle-generated seismograms recorded under summer and

model. Automatic vehicle classification algorithms will have to account for these effects if the algorithms are to operate successfully in the presence of snow

CRYSTALLINE STRUCTURE OF UREA ICE SHEETS USED IN MODELING EXPERIMENTS IN THE CRREL TEST BASIN.

Gow, A.J., Sep. 1984, 48p., ADA-146 434, 29 refs.

ICE CRYSTAL STRUCTURE, UREA, SEA ICE, ICE MECHANICS, GRAIN SIZE, ICE MODELS,

ICE MECHANICS, GRAIN SIZE, ICE MODELS, ICE SHEETS, TESTS.
This report describes the growth characteristics and crystalline textures of urea ice sheets which are now used extensively in the CRREL test basin for modeling sea ice. The aims of the report are to describe the different kinds of crystalline texture encountered in urea ice sheets and to show that even small variations in texture can drastically influence the mechanical behavior of urea ice sheets. Standard petrographic techniques for studying microstructure in thin sections were used on 24 urea ice sheets. These investigations entailed observations of the crystalline texture of the ice (including details of the subgrain structure), grain size measurements, and studies of the nature and extent of urea entrapment and drainage patterns in the ice. Increased knowledge of the factors controlling the crystalline characteristics of urea ice sheets has progressed to the point where test basin researchers at CRREL are now able to fabricate ice sheets with prescribed structures leading to fabricate ice sheets with prescribed structures leading to predictable mechanical properties

FAIRBANKS.
Radar and wide-angle reflection and refraction (WARR) profiles were obtained across three buried sections of the trans-Alaska pipeline near Fairbanks in late April 1983. A broad-band, pulsed radar operating in the VHF (seep high frequency) range was used. The surficial geology at the three sites consisted of gravel (dredge tailings) silt and alluvium, respectively, and the sites we e-marginally frozen or completely thawed. At the gravel set the pipe (approximately 2 m deep) and an underlying water table were easily sible. There was no radar signature of the pipe at the silt site the WARR profiles verified the high absorption of the material. The response was marginal at the alluvium tie. High absorption due to thawing or marginal freezing conditions about the pipe makes radar a generally poor choice for mapping freeze-thaw boundaries but a good choice for estimating material state and moisture content. estimating material state and moisture content

POLYETHYLENE GLYCOL AS AN ICE CONTROL COATING.

IMPACT OF SLOW-RATE LAND TREATMENT ON GROUNDWATER QUALITY: TOXIC OR-GANICS.

Parker, L.V., et al, Dec 1984, 36p., ADA-153 253, Refs. p 19-21.

Jenkins, T.F., Foley, B.T.

GROUND WATER, WASTE TREATMENT, WATER TREATMENT, LAND RECLAMATION. SEEPAGE, ORGANIC NUCLEI, ENVIRONMEN TAL IMPACT.

The removal efficiency for 16 organic substances ii. wastewater was studied on an outdoor, prototype slow-infiltration system. The initial concentration of each of these substances in the wastewater was approximately 50 microgram/L. Removal was via volatilization during spray application and subsequent adsorption in the soil. The percent removal during spraying could be estimated from the liquid-phase transfer coefficient, losses were up to 70% for the most volatile components. The total percent removal for the system, based on the concentration in the percolate, was more than 98% for all substances. Only chloroform, which has a low octanol-water coefficient and according to the iterature is not degradable aerobically, was continuously detected in the percolate. The major final removal mechanisms are believed to be volatilization and biodegradation-internation from the percolate. The major final removal mechanisms are believed to be volatilization and biodegradation early spring as a result of application during the colder months was also observed. The two substances that were most persistent in the soil were PCBs and dethylphthelate. The removal efficiency for 16 organic substances in wastewater months was also observed. The two substances that were most persistent in the soil were PCBs and dethylphthalate PCBs were apparently slowly lost from the system, probably by volatilization. The behavior of diethylphthalate was different in the two soils tested but was more recalcitant. than expected

CR 84-31 DETECTION OF BURIED UTILITIES. VIEW OF AVAILABLE METHODS AND A COM-PARATIVE FIELD STUDY.

Henry, K.S., Arcone, S.A. 39-2918

UNDERGROUND FACILITIES, UTILITIES, DETECTION, FROST PENETRATION, MAGNETIC SURVEYS, GEOPHYSICAL SURVEYS, EARTH-

Locating buried utilities is often necessary for repair, servicing or prevention of damage when earthwork is to be conducted in a particular area. Of the many methods available for detection of buried utilities, those in most wide-spread use are magnetic induction, magnetometry, and radiofrequency tracking. Comparative field tests of 11 locators using these three operating methods were conducted in Hanoster New Hampshire and eight of these were further tested at the U.S. Military Academy, West Point, New York, and the Stewart Army Subport Newburgh, New York. At West Point and Newburgh, the nine sites included a variety of utility types including iron and steel pipe cable, sitreous

tile and plastic, as well as different terraln and groundcover tile and plastic, as well as different terrain and groundcover characteristics. Tests with the radiofrequency tracking locators were insufficient to evaluate their ability to locate nonmetallic pipe or to judge if one locator was superior to the other. Although not statistically different, slightly more accurate average readings were obtained with the magnetic induction and magnetometer instruments over cable than over pipe. Shallow utilities (<.3.5 ft) were located slightly more accurately than deeper ones. In general, the low-to mid-priced magnetic induction locators appeared to be most cost effective. Problems with accuracy in utility location occurred mainly at sites with steep topography or where utilities were in very close proximity. Successful where utilities were in very close proximity Successful operation of the instruments required only a small amount of training

CR 84-32 SHORELINE EROSION PROCESSES: ORWELL

LAKE, MINNESOTA.

METEOROLOGICAL FACTORS.

Orwell Lake, in west-central Minnesota, is a flood-control, water-management reservoir first impounded in 1953 Subsequent erosion of the shoreline and a lack of knowledge of slope erosion processes in this region prompted this study to identify and quantify the processes there The processes were measured at selected sites between June 1980 and June 1983 Erosion of the banks is primarily caused by three processes rain, frost thaw, and waves. The first two processes tend to move sediment to the base of the steen slopes forming a relatively eartify surface of accumulafirst two processes tend to move sediment to the base of the steep slopes, forming a relatively gentle surface of accumulation. Wave action then tends to move this sediment into the lake. Analysis of the data collected over three years has confirmed that wave action is the dominant crossion process, providing almost 7° c of the erosion during the 1981-82 study year. During the 1981 high pool level, 2,089 Mg of sediment, morely colluvium, was removed from the lower slopes by wave action rinking the 162 km of circling shoreline. More than 2,300 Mg was croded by waves accompanying the higher pool levels of 1982

ANALYSIS

An inexpensive drill has been modified to provide researchers with the ability to auget an open hole of to acquire continuous undisturbed "6-min-diam core samples of a variety of perennially forzen materials that are suitable for chemical and petrographic analysis. It was developed by field testing in support of research from 1930 to 1933. Operation of the drill is hased mainly on using a minimum of power to cut chrough forzen ground with tungsten carbide cutters on a CRR11 coting auger. The nec content, temperature and grain size of the frozen sediments are important satiables determining the sampling depth. Perennially forzen sediments with temperatures in the range of 0.5.0 to 3.5.

Drilling C have been continuously cored with this drill. Drilling and sampling are most efficiently conducted when ambient air temperatures are below freezing and the active layer air temperatures are below freezing and the active layer is frozen. The self-contained lightweight drill is readily anisportable off-road by helicopter or tracked vehicle, or by towing over roads. It is locally self-mobile by use of a winch. Total cost of the drill and modifications is estimated at approximately \$10,000

EFFECT OF NONUNIFORM SIZE ON INTER-NAL STRESSES IN A RAPID, SIMPLE SHEAR PLOW OF GRANULAR MATERIALS. PART 1. TWO GRAIN SIZES

Shen, H H., Feb. 1985, 18p., ADA-154 045, 18 refs.

SHEAR FLOW, PARTICLE SIZE DISTRIBUTION, MICROSTRUCTURE, MATERIALS, STRESSES, STRAINS, AVALANCHE MECHANICS, MATH-**EMATICAL MODELS**

Existing theories that predict the stress-strain rate relationship Existing theories that predict the stress-strain fate relationship in a rapidly sheared granular flow can only treat macerials that are made of single-size particles. However, granular flows usually involve materials of mixed sizes. It has been observed in many laboratory studies that size distribution has a significant effect on the flow of a granular material. Despite its importance, no quantitative theory has been devised that can explain the effect of size distribution. An analytical model is deviated by the research in my first the discrete in a my first. that can explain the effect of size distribution. An analytical model is developed here to quantify the stresses in a mixture of spheres with two different sizes and identical material properties. Binary collisions between adjacent particles are considered as the dominating stress-generating mechanism. Comparisons between the theoretical results and the existing laboratory data show good agreement.

EFFECT OF NONUNIFORM SIZE ON INTER-NAL STRESSES IN A RAPID, SIMPL). SHEAP FLOW OF GRANULAR MATERIALS. PART 2. MULTIPLE GRAIN SIZES.

Shen, H.H., Feb. 1985, 20p., ADA-154 046, 19 refs.

SHEAR FLOW PARTICLE SIZE DISTRIBUTION. MICROSTRUCTURE, STRESSES, MATERIALS, SHEAR STRESS.

In the past all theoretical analyses for rapidly sheared granular flows assumed that the granular solids are either disks or spheres and are uniform in size. However, natural materials that create these granular flows are in general irregular in shape and have various spectra of sizes. The stress and rate of energy dissipation levels in granular flows are significantly influenced by the size distribution. In part 1 of this report series (see 40-38, CR 85-2) the formulation of the report series (see 40-38, CR 85-2) the formulation of the constitutive equations considering a two-size granular mixture is presented, where the ratio of the two sizes is nearly one. Here, in part 2, the constitutive equations for a two-size mixture are extended to include a general size ratio. In addition, a complete spectrum of size distribution is incorporated, which allows the quantification of the size distribution effect in the most general way. In analyzing the stresses, intergranular collision is assumed to be the is incorporated, which allows the quantification of the size distribution effect in the most general way. In analyzing the stresses, intergranular collision is assumed to be the major dynamic activity at the microscopic level. Because of the present limited knowledge of treating shape effects, the analysis is confined to the flow of either disks or epheres. The result of this work provides necessary information for a more realistic analysis of natural and industrial granular flow.

ICE SOLID INTERFACE, ICE FRICTION, ICE HARDNESS, SURFACE ROUGHNESS, ENGINEERING, VELOCITY, TESTS.

NEERING, VELOCITY, TESTS.

This study investigates the relative influence of various parameters on the kinetic friction coefficient between ice and different surfaces. Friction tests were performed with urea-doped, columnar ice, studying the parameters of normal prissure, velocity, type of material roughness, ice orientation, ice hardness and test configuration. Tests were conducted by pulling a sample of ice over a sheet of material and by pulling a sample of material over an ice sheet. An ambient temperature of -1.5 was maintained throughout, and the ce surface hardness was measured usin, a specially designed apparatus. The results of the friction tests revealed that the behavior of kinetic friction coefficient with varying velocity was significantly influenced by the test configuration and material roughness. The magnitude of the kinetic friction cuefficient was also affected by varying normal pessure, surface roughness and ice hardness. Additional guidelines for standardized ice friction tests and future investigations are recommended. are recommended.

METAMORPHISM (SNOW)

METAMORPHISM (SNOW)

Large temperature gradients applied to a snow over drive water vapor upwards and result in rapid recrystallication of snow crystals. The same temperature gradients create gradients of air density that can cause flows of air through the snow cover. The formalism necessary to describe these flows is developed here in an ifort to include the convention of vapor in the understanding of snow metamorphism. The theory of convection through purous media

is extended to include the transport of water vapor, which is important because of its latent heat. Results are presented in terms of a Lewis number, defined as the ratio of thermal mass difficulties For Lewis numbers greater than to mass diffusivities. For Lewis numbers greater than 16, phase change intensifies convection, and for Lewis numbers less than 1.0, phase change retards convection. Two boundary conditions of special interest in the study of snow, 2 constant heat flux bottom and a permeable top, are investigated. ed.

REVIEW OF METHODS FOR GENFRATING SYNTHETIC SEISMOGRAMS.

REVEGETATION. TUNDRA. SOIL EROSION, ENVIRONMENTAL PROTEC-TION, ACTIVE LAYER, VEGETATION, FROST ACTION, CLASSIFICATIONS, LANDFORMS, ENVIRONMENTAL IMPACT.

ENVIRONMENTAL IMPACT.
The or-ersity of disturbance types, landforms, vegetation and soils, together with the large, well-documented flors, makes Cape Thompson an ideal site to study long-term (20-year) environmental adjustments after impact. Mancaused disturbances there between 1958 and 1962 fall into a cettegories: runways, excavations and off-road vehicle rails. In addition, natural disturbance by frost action creates scars. Reestablished vegetation after 20 years consisted of species found in adjacent undisturbed landscapes.

ANALYSIS OF RIVER WAVE TYPES.

Ferrick, M.G., June 1985, 17p., ADA-158 683, For another source see 39-3098. 20 refs. 40-1050

WATER WAVES, RIVER FLOW, RIVER ICE. DAMS, UNSTEADY FLOW, ICE JAMS, RUNOFF, FRICTION, MATHEMATICAL MODELS.

FRICTION, MATHEMATICAL MODELS.
In this paper we consider long-period, shallow-water river waves that are a consequence of unsteady flow "vive, waves result from hydroelectric power generation or flow control at a dam, the breach of a dam, the fination or release of an ice jam, and rainfall/runnoff process. The Saint-Venant equations are generally used to dei the more waves. Dynamic, gravity, diffusion, and kinematic inversals have been defined, each corresponding to different is not subset of the overall range of river hydraulic properties and time scales of wave motion. However, the parameter and a corresponding to each wave description are not well defined, and the transitions between wave types have not been explored. This paper is an investigation into these areas, which are fundamental to river wave modeling. The analysis is based on the concept that river wave behavior is determined by the halance between friction and inertia.

ELECTROMAGNETIC MEASUREMENTS OF MULTI-YEAR SEA ICE USING IMPULSE RA-DAR.

SEA ICE, ELECTROMAGNETIC PROPERTIES. ICE BOTTOM SURFACE, MARINE GEOLOGY, GEOPHYSICAL SURVEYS, ELECTRICAL RESIS-TIVITY, BRINES, DIELECTRIC PROPERTIES

Sounding of multi-year sea u.e. using impulse radar operating in the 80- to 800 MHz frequency band, has revealed that the bottom of this rice cannot always be detected. This paper diseases a field program aimed at finding out why this is so, and at determining the electromagnetic (but his properties of multi-year sea use. It was found that the

bottom of the ice could not be detected when the ice structure had a high brine content Because of brine's high conductivi-ty, brine volume dominates the loss mechanism in first year sea ice, and the same was found true for multi-year year sea ice, and the same was found true for multi-year ice. A two-phase dielectric mixing formula, used by the authors to describe the EM properties of first-year sea ice, was modified to include the effects of the gas pockets found in the multi-year sea ree

VEGETATION AND ENVIRONMENTAL GRADIENTS OF THE PRUDHOE BAY REGION,

ALASKA. Walker, D.A., Sep. 1985, 239p., ADA-162 022, Refs.

TUNDRA, VEGETATION, TEMPERATURE GRADIENTS, PLANTS (BOTANY), COASTAL TOPOGRAPHIC FEATURES, ICE WEDGES, SNOW DEPTH, TEMPERATURE EFFECTS, LOESS, HUMMOCKS, SOIL WATER, UNITED STATES-ALASKA,

STATES—ALASKA.

The Prudhoe Bay region is a particularly interesting area of tundra because of its well-defined and steep environmental gradients, the combination of which has not been described elsewhere in the Arctic. It is a region of wet coastal tundra that has a inque substrate pH gradient, due in part to its coastal location. The prevailing northeast winds distribute loess from the Sagavanirktok River over most of the region. Areas downwind from the river have alkaline tundra with a gradient of declining soil pH values away from the river the northwest portion of the region is not downwind from the river and consequently has acidic tundra. The coastal temperature gradient is among the steepest in the Arctic. Three of Youngs (1971) four floristic zones, which are based on the amount of 'otal summer warmth, are present within the region. The effects of the temperature gradient can be seen in the increase of the total number of plants in the flora and the increased plant productivity, particularly of shrubs, as one moves inland. The predominantly wet landscape also creates steep vegetation gradients within elevation changes of a few centimeters. Small hummocks and higher microsites associated with ice wedge polygon relief may be elevated only 10-25 cm above the level of saturated soils but can support rich mesic tundra plant communities.

TION, ABSORPTION, TESTS

A method fe, the analysis of TNT, RDX and HMX explosives it solts and sediments has been developed. It consists of methanol extraction followed by reversed-phase high performance liquid chromatography using 10% acctometric 40% methanol 50% water as the cluant. This method was used to study the effect of various drying techniques upon the recovery of TNT. RDX and HMX from soil and sediment samples contaminated with high (%) and low (interogram g) levels of these explosives. For highly contaminated samples, complete recovery of TNT and RDX was oblained using fiveze drying while air drying at room temperature resulted in greater toxin, such as onen drying at 105C, oven drying at 45C, microwave oven drying, and drying under infrared lamps all resulted in greater loxes, with TNT and RDX recoveries ranging from 76 to 90%. Drying losses were not due to simple volatilization but rather to chemical reaction and or sorption. For soil and sediment samples containing low levels of TNT, RDX and HMX recoveries of all three explosives were quantitative for all of the above drying techniques. technique

YSIS (MATHEMATICS).

Concern over the environmental fate of explosives has brought about development of sensitive analytical methods for measuring them in groundwater. In turn this concern has been extended to validating the sampling procedures for groundwater. This report addresses the potential effects of residual drilling muds on the analysis for explosive contaminants (TNT, DNT, RDX and HMX) in monitoring wells. The approach was to determine sorption isotherms for each contaminant. Sorption appeared to be independent of solids concentration. Linear isotherms were obtained for RDX and HMX over a range of analytic concentrations, therefore, a single constant can be used to estimate the amount sorbed when the solution concentration is known. Isotherms for TNT and DNT were not linear, however. Scatchard analysis suggested that the isotherms for these analytes could be resolved into two predominant components: a linear component suggested that the isotherms for these analytes could be resolved into two predominant components: a linear component above a certain sorbed quantity and a Langmur-type component below this quantity. The experimental data were fitted by regression analysis using the appropriate model. The equations developed can be used to predict the sorbed fraction (analytical bas) for any combination of solids and analyte concentration. The amounts of bentonite found in some existing wells do not appear to be sufficient to cause significant buss in analyses for these explosive contaminants

MODELS.
Ground-probing radar can be an effective tool for exploring the top 10 to 20 m of ground, especially in cold regions where the freezing of water decreases signal absorption. However, the large electrical variability of the surface, combined with the short wavelengths used, can often cause severe ground clutter that can mask a desired, deeper return in this study a model facility was constructed consisting of a metallic reflector covered by sand. Troughs of saturated sand were emplaced at the surface to vary surface electrical properties and to act as a noise source to interfere with the bottom reflections. Antenna polarization and height, and signal stacking in both static (antennas stationary) and dynamic (antennas moving) modes were then investigated as methods for reducing the surface clutter parallel to the profile direction (perpendicular to the troughs' axes) gave profiles superior to the perpendicular case because of the directional sensitivity of the antenna radiation

COMPUTER APPLICATIONS, TESTS.

Stresses developed in a rapid, simple shear flow of disks are quantified. Collisional momentum transfer is considered to be the dominant stress generating mechanism. The disks are inelastic and frictional. The restitution coefficient and the coefficient of friction together determine the transfer of momentum and dissipation of energy during a collision. The frictional coefficient generates and maintains a rotational motion of disks. The total fluctuation motion of disks consists of two translational modes and one rotational mode. The rotational mode is found to depend on both the restitution and friction coefficient. Equipartitions of energy among all modes of motion is absent. The mean rotation, however, depends only on the mean flow gradient. The analysis assumes a constant magnitude for all fluctuation modes. Comparison with a computer simulated disk flow shows good agreement. This implies that the distribution of stresses.

BRITTLENESS OF REINFORCED CONCRETE STRUCTURES UNDER ARCTIC CONDITIONS. Kivekis, L., et al. May 1986, 20p., ADA-170 792, 9

Korbonen, C

41-213 REINFORCEL CONCRETES, BRITTLENESS, CONCRETE STRUCTURES, TRANSPORTATION, COLD WEATHER TESTS, CRACKING (FRACTURING)

The behavior of reinforced and unreinforced concrete beam The behavior of reinforced and unreinforced concrete beams was studied under impact loading at low temperatures, and the results were compared to the behavior of reinforcing steel (rebar) in Charpy-V impact tests. Transition temperatures as low as -30 C were obtained for the rebars in the Charpy-V tests, whereas no brittle failures occurred in the rebars in the reinforced concrete beams at temperatures as low as -60 C, even in beams where the rebars were intentionally notched. The impact strength of unreinforced concrete increases considerably at lower temperatures, thus reducing cracking of reinforced concrete structures and significantly increasing the safety of lightly reinforced structures.

EXPERIMENTAL DETERMINATION OF HEAT TRANSFER COEFFICIENTS IN WATER FLOW-ING OVER A HORIZONTAL ICE SHEET. Lunardini, V.J., et al, June 1986, 81p., ADA-170 427,

FLOW.

Experiments to study the melting of a horizontal ice sheet with a flow of water above it were conducted in a 35-m-long refrigerated flume, with a cross section of 1.2x1.2 m. Water depth, temperature, and velocity were varied as well as the temperature and initial surface profile of the ice sheet. The heat transfer regimes were found to consist of forced turbulent flow at high Reynolds numbers with a transition to free convection heat transfer. There was no convincing evidence of a forced laminar regime. The data were correlated for each of the regimes, with the Reynolds number, Re, or the Grashof number combined with the Reynolds number.

ROADS, FROZEN GROUND STRENGTH, FREEZE THAW CYCLES, GROUND THAWING, PAVEMENTS, SOIL STRENGTH, SUBGRADE SOILS, LOADS (FORCES), UNFROZEN WATER CONTENT, STRESSES, SOIL WATER.

This work is the first of a series of four reports about laboratory and field testing of various granular road and artifeld subgrades and analysis of six soils from a test site in Winchendon, Massachusetts. Repeat load triaxial tests were done on fozen and thawed soils to characterize the variations in frozen and thawed soils to characterize the variations in their resilient properties throughout the seasons. Linear regression yielded empirical equations relating the resilient modulus to applied stress, unfrozen water content (for frozen soils), moisture tension (for thawed soils) and density. Equipment and test procedures (given in detail) were developed that allowed simulation in the laboratory of the gradual recovery of stiffness that occurs in the field after thawing. The resilient moduli were strongly dependent on soil state, dropping at least two orders of magnitude upon thawing.

CR 86-05 EFFECT OF GRAIN SIZE ON THE INTERNAL FRACTURING OF POLYCRYSTALLINE ICI Cole, D.M., July 1986, 71p., ADA-171 571, Refs.

TOGRAPHY, STRESSES.

FRACIONING. GRAIN SIZE, ICE CREEP, PHOTOGRAPHY, STRESSES.

This work presents the results of a study to examine the effects of grain size on the number and size of internal interofractures in polycrystalline ice.

Laboratory-prepared specimens were tested under uniaxial, constant-load creep conditions at -5 C. Grain size ranged from 15 to 60 mm. This range of grain size, under an initial creep stress of 20 MPa, led to a significant change in the character of deformation. The finest-grained material displayed no internal cracking and typically experienced strains of 1/100 at the minimum creep rate. The coarse-grained material experienced severe cracking and a drop in the strain at the minimum creep rate to approximately 4/100. Extensive post test optical analysis sillowed estimation of the size distribution and number of microcracks in the tested material. These data led to the development of a relationship between the average crack size distribution, when normalized to the first indicate that the average crack size is approximately one half the average grain diameter over the stated grain size range. A dislocation pileup model is found to adequately predict the onset of internal cracking. The work employed acoustic emission shed light on the time and strain at which

the fracturing began and when the peak fracturing rate oc-curred. Other topics covered in this report include creep behavior, crack healing, the effect of stress level on fracture size and the orientation of cracked grains. Theoretical aspects of the grain size effect on material behavior are also given.

SEWAGE TREATMENT, WATER POLLUTION,
CLIMATIC FACTORS, FILTERS, SLUDGES

CLIMATIC FACTORS, FILTERS, SLUDGES
Nitrogen control in the form of ammonia removal or conversion is required, or will be required, for a significant number of military wastewater treatment systems. This report presents a summary of engineering criteria for those processes in most common use at military facilities in the cold regions. These processes include: trickling filters, treatment ponds, rotating biological contactors (RBC) and activated sludge. A design example is presented for each case. All four processes can achieve significant levels of ammonia memoval or conversion. If ammonia discharge limits are 0.5 mg/L or less it may be necessary to use the activated sludge process. Trickling filters or RBC units are recommended for higher (> 1 mg/L) discharge limits. Pond systems are suitable for seasonal ammonia removal in cold climates.

APPLICATIONS OF THE FINITE-ELEMENT METHOD TO THE PROBLEM OF HEAT TRANSFER IN A FREEZING SHAFT WALL. Liandi, F., Aug. 1986, 24p., ADA-172 552, 12 refs.

41-595 SOIL FREEZING, SHAFTS (EXCAVATIONS), HEAT TRANSFER, TUNNELS, WALLS, LATENT HEAT, HEAT CAPACITY, ANALYSIS (MATH-EMATICS).

EMATICS).

In this work, numerical computations of heat transfer for freezing a shaft wall have been conducted. Both fixed mesh and deforming mesh finite-element methods are used in the fixed mesh method, latent heat effects are accounted for through a delta function in the apparent heat capacity. In the deforming mesh method, an automatic mesh-generation technique with transfinite mappings is used, and in this method two different approaches are taken to evaluate the movement of the interface. The freeze-pipes are considered as point sources with irregular distribution. The advancement of the inner and outer boundaries of the frozen wall is found to be in agreement with the previously computed results.

p.17-19. 41-1263

SNOW SURFACE, SEA ICE, HEAT TRANSFER,

MOISTURE TRANSFER, SURFACE ROUGH-NESS, TURBULENT FLOW, MODELS, WIND VELOCITY, LATENT HEAT

VELOCITY, LATENT HEAT

The bulk aerodynamic transfer coefficients for sensible, C(H)
and latent, C(E), heat over snow and sea ice surfaces are
necessary for accurately modeling the surface energy budget
but are very difficult to measure This report therefore
presents a theory that predicts C(H) and C(E) as functions
of the wind speed and a surface roughness parameter. The
crux of the model is establishing the interfacial sublayer
profiles of the scalars, temperature and water sapor, over
aerodynamically smooth and rough surfaces. These interfaciall sublayer profiles are derived from a surface-renewal
model in which turbulent eddies continually sweep down
to the surface, transfer scalar containmants across the interface
by molecular diffusion, and then burst away. Matching
the interfacial sublayer profiles with the usual semilogarithmic

inertial sublayer profiles yields the roughness lengths for temperature and water vapor. With these and a model for the drag coefficient over snow and sea ice based on actual measurements, the transfer coefficients are predicted. C(E) is always a few percent larger than C(H). Both decrease monotonically with increasing wind speed for speeds above 1 m/s, and both increase at all wind speeds as the

TION, SOIL WATER, FREEZE THAW TESTS.

Three methods for determining the frost susceptibility of soils are evaluated in this report. These methods are the U.S. Army Corps of Engineers frost design soil classification system, a moisture-tension/hydraulic-conductivity test, and a laboratory freeze-thaw test. The Corps method, which is based on particle size, soil classification, and a laboratory freezing test, was found to be useful for identifying frost-susceptible soils. However, it cannot be used with confidence for determining the degree of frost susceptibility. The moisture-tension/hydraulic-conductivity test was found to be unacceptable because it required too much time and its results correlated poorly with field observations. The freeze-thaw test was determined to be the most accurate of the methods studied, including the freeze-thaw test that is a part of the Corps method. The freeze-thaw test is thoroughly described. It includes indexes of both frost-have susceptibility (heave rate) and thaw-weakening susceptibility (CBR after thawing). It also accounts for the effects of freeze-thaw eyeling and is completely automated to improve the repeatability of the test results.

It is suggested that the Corps freezing test.

PLANTS (BOTANY). SOIL POLLUTION. PLANT PHYSIOLOGY, WASTE DISPOSAL, CHEMICAL ANALYSIS, TESTS, GROWTH, ROOTS

PHYSIOLOGY, WASTE DISPOSAL, CHEMICAL ANALYSIS, TESTS, GROWTH, ROOTS
Little is known about the response of terrestrial plants to 2.4.6-trinitrotolisene (TNT) The objectives of this study were to develop and test a method for measuring the amounts of TNT and its metabolites in plant tissue and to assess their effects in yellow nucleage (Cyperus esculentus L). The method eveloped was tested for its precision and accuracy for measuring TNT and its metabolites. The minimum detection limits of the method were 0.4. 0.6 and 0.9 mg/kg for TNT, 4-ADNT and 2-ADNT, respectively. Homogenization of plant tissue prior to analysis did not improve precision or recovery of naturally incorporated residues. Spake recoveries ranged from 46°- to 101°- Two plant growth and uptake studies were conducted by growing nutsedge in hydroponic cultures containing TNT concentrations ranging from 0 to 20 mg. L. The greatest changes in physiological growth of 20 mg. L. The greatest changes in physiological activity occurred between solution concentrations of 0.5 and 50 mg. L. The greatest changes in physiological effects from TNT may occur at levels below 0.5 mg. L. Root growth was affected most, followed by rhyromes and leaves: TNT and metabolites were found throughout the plant. Since TNT was the only compound present in the cultures, the metabolites must have been formed within the plant. Increasing the TNT concentrations of all 1 compounds were greatest in the roots, while the thiromes contained the greatest of the roots, while the thiromes contained the greatest of the roots, while the thiromes contained the greatest of the roots, while the thiromes contained the greatest of the roots, while the thiromes contained the greatest of the roots, while the thiromes contained the greatest of the roots while the thiromes contained the greatest of the roots while the thiromes contained the greatest of the roots of the concentrations of all 1 compounds were greatest in the roots, while the thiromes contained the greatest

TRIAXIAL TESTING OF FIRST-YEAR SEA ICE. Richter-Menge, J.A., et al, Dec. 1986, 41p., ADA-178

Cox, G.F.N., Perron, N., Durell, G., Bosworth, H.W.

ICE STRENGTH, ICE MECHANICS, ICE CRYS-

TAL STRUCTURE, SEA ICE, YOUNG ICE, COM-PRESSIVE PROPERTIES, STRAIN TESTS, LOADS (FORCES), TEMPERATURE EFFECTS This report presents the first series of conventional trianal tests carried out on columnar first-year sea ice samples obtained from the field and tested under controlled laboratory obtained from the field and tested under controlled laboratory conditions using a large-capacity test machine. A total of 110 horizontal ice samples from Prudhoe Bay, Alaska, were tested on a closed-loop electro-hydraulic test machine at -10 C in unconfined and confined constanti-strain-rate compression. The confined tests were conducted in a conventional triaxial cell that maintained a constant ratio between the radial and axial stress to simulate in situ loading conditions. The load ratios used were 0.25, 0.50 and 0.75. The strain rate of each test was constant at 1/100, or 1/100.000 per sec Data are presented on the strength, failure strain and initial tangent modulus of the first-year sea ice under these loading conditions. The effects of confining pressure, strain rate and ice structure on the mechanical properties of the ice are examined.

ATMOSPHERIC ICING ON COMMUNICA-TION MASTS IN NEW ENGLAND.

Mulherin, N., Dec. 1986, 46p., ADA-178 347, 34 refs. 41-3142

ANTENNAS, ICING, TOWERS, ICE FORMATION, PRECIPITATION (METEOROLOGY). COST ANALYSIS.

Rime seing and freezing precipitation are of concern to the radio and television broadcasting industry. This report contains the results of a study seeking to document the severity and extent of transmitter tower using and related problems in the northeastern United States Information problems in the northeastern United States Information was obtained via mail questionnaire and telephone interviews with 85 station owners and engineers concerning 118 different stations. Results show that television and Fab broadcasters are seriously impacted by tower scing, however, AM operators are usually not affected by expected New England scing levels. Combined annual costs for scing protection and icing-related repairs averaged \$121, \$402 and \$3066 for AM. FM and TV stations respectively. None of the AM stations polled employ any icing protection measures whereas all the TV stations do. The percentage of FM stations having scing protection in the three northern states averaged \$0%, indicating a significant concern for scing in that region. In contrast, the percentage of FM stations with icing protection was 63.5% for the southern New England states. The usage of guyed versus non-guyed towers was a poor indicator of icing costs. However, the factors of increasing mast height and mast top clevation are significant to increasing mast height and mast top clevation are significant to increasing costs.

FROST ACTION
Findings from a sur-year field and laboratory program of frost-action research in four areas are summarized. Research on the first topic, frost-susceptibility index tests, led to selection of the Corps of Engineers frost design soil classification system as a useful method at the simplest level of testing. At a much more complex level, a new freezing test combined with a CBR test after thawing is recommended as an index of susceptibility to both frost heave and thaw weakening. Under the second topic, a soil column and dual gamma system were developed and applied to obtain soil data used in improving and validating a mathematical model of frost heave, the objective of the third topic. The model was effectively improved, a probabilistic component was added, and it was successfully tested against field and laboratory measurements of frost heave. A thaw consolidation all gorithm was added which was shown to be useful in predicting the seasonal variation in resilient medium of granular soils. gottom was asset which was shown to be useful in peracting the seasonal variation in festilent medulus of granular soils, the objective of the fourth topic. A laboratory testing procedure was developed for assessing the resilient modulus of thawed soil at various stages of the recovers process, as a function of the applied stress and the soil mostitute tension, which increases as the soil gradually desaturates during recovery. The procedure was salidated by analyzing testing the soil graduality desaturates. deflections measured on pavements by a falling weight deflec-tometer. Frameworks for implementing findings from the principal research topics are outlined.

RIME METEOROLOGY IN THE GREEN MOUNTAINS.

Ryerson, C C., Jan. 1987, 46p , ADA-178 358, 33 refs.

ICING, HOARFROST, ANTENNAS, ICE DETECTION, SYNOPTIC METEOROLOGY, METEOROLOGICAL FACTORS, MOUNTAINS, VARIATIONS.

Rime icing is a frequent and severe problem in high: clevations of the Green Mountains because it impacts radio and television antennas and ski lifts and could affect high elevation wind machine performance. Rime meteorology, measuring equipment performance, and variation with elevation were analyzed statistically on Mt. Mansfield and Madonian Peak, Vermont, during the winters of 1982-83 and 1983-84. Weather conditions were measured from surface weather observations, from rawinsonde 850 mt records, and from synoptic weather maps. Rime intensity with time was measured with a Rosemount antenna decing system on Mt. Mansfield, and time accretion was measured from collectors installed from 643 to 1227 m on the two peaks. Most rime events in the Green Mountains are of low intensity, with greatest intensities found in warmer, subfreezing air within 5 C of the dew point. Rime was usually most intensic within deep low pressure systems, and was associated with 9- to 10-tenths cloud cover and light precipitation. Rime was variefly associated with high pressure. Most rime events occurred within cold and occluded fronts in southerly to westerly winds. Rime icing is a frequent and severe problem in higher elevations

PAVEMENTS. FREEZE THAW TESTS, SUB-GRADE SOILS, AIRPORTS, ROADS, UNFROZ-EN WATER CONTENT, SOIL WATER, TEMPER-ATURE EFFECTS.

ATURE EFFECTS.

This is the third in a series of four reports on the laboratory and field testing of a number of road and airfield subgrades, covering the laboratory repeated-load transal testing of five soils in the frozen and thawed states and analysis of the resulting resilient medulus measurements. The laboratory testing procedures allow simulation of the gradual increase in stiffness found in frost-susceptible soils after thawing. The resilient modulus is expressed in a nonlinear model in terms of the applied stresses, the soil mosture tension level (for unfrozen soil), the unfrozen water content (for frozen soil) and the dry density. The resilient modulus about 10 GPa for the frozen material at temperatures in the range of -5 to -8 C. The decrease in modulus with increasing temperature was well-modeled in terms of the unfrozen water content. Upon thaw, the modulus dropped to about 100 MPa and generally increasing principal stress ratio. The modulus also increased with increasing principal stress ratio. The modulus also increased with the soil mosture tension level. The resilient Possion ratio did not appear to be a systematic function of any of the test variables.

MECHANICAL PROPERTIES OF MULTI-YEAR SEA ICE. PHASE I: ICE STRUCTURE ANAL-

PRESSURE RIDGES, ICE FLOES, TESTS.

This report describes the structural analysis of multi-year sea ice samples that were tested in the first phase of a program designed to obtain a comprehensive understanding of the mechanical properties of malti-year sea ice from the Alaskan Beaufort. Sea — Each test specimen is classified into one of three major ice testure categories, granular, columnar, or a mixture of columnar and granular see. The crystallographic orientation, percent columnar ice, and grain are are then evaluated for the granular and or columnar ice in the sample. Test results are interpreted with respect to these parameters. The overall composition of multi-year ridges is also considered, based on the extensive field sampling that was done in the program.

CRYSTAL STRUCTURE AND SALINITY OF SEA ICE IN HEBRON FIORD AND VICINITY, LAB-

Gow, A.J., Mar. 1987, 18p., ADA-180 930, 15 refs

ICE CRYSTAL STRUCTURE, ICE SALINITY, SEA ICE, MELTWATER, OCEAN CURRENTS, BRINES, PHOTOGRAPHY, CANADA LABRA-HEBRON FIORD

Resorts of measurements of the crisitalline structure and salin to characteristics of sea ice in Hebron Front and society

are presented. Structurally, the fiord see was entirely first-year and composed predominantly of congelation, columnar-type crystals. At most of the sampling sites the see exhibited moderately to atrongly aligned c-axes consistent with the inferred direction of near-surface currents in the fiord. Generally diminished values of bulk salinity at five separate locations reflect the warm ice conditions encountered at the time of sampling (late May), and the effect of meltwater flushing in promoting loss of brine, vertically, from the ice sheet. Observations outside Hebron Fiord indicated the presence of only minor amounts of multiyear ice during the latter part of May.

PLICATIONS, FOREST LAND.

Measurements of snow depth and its water equivalent were obtained at 11 snow courtes in the Allagash. Maine, area in conjunction with the acquaistant of five Landast-2 and -3 images during the 1977-78 and 1978-79 winters. To test a hypothesis that Landast reflected radionce values on a regional scale do change, histograms of the Landast MSS band 7 reflected radionce values for a 300 x 300 pixel (420 sq km) area near Allagash were evaluated to quantify the change. A statistical description (skewness and kurton) of the histogram for each scene was developed and then correlated with ground measurements of snow depth. A new index based on skewness and model population was found to carrelate well with snow depth. Following these initial results, the Landast data were re-examined and corrections were made for solar elevation and MSS sensor calibration. The reflected radiance from open areas showed a consistent increase in intensity with increasing snow depth. The forested land cover classes did not change with snow depth.

VOLUME), TEMPERATURE EFFECTS.
Soli-moter potential was measured on three soils and influencing factors, including water content, soil tenture, dey density and temperature, were investigated. The soil-water potential in unsaturated, unfrozen soils decreases with decreasing soil tenture content and soil dispersion, and increases with increasing temperature and dry density. Unfrozen water contents at a given temperature were investigated. Of these three factors, only increasing the salt concentration caused a large change in the unfrozen water versus temperature curves. Water migration in an unsaturated frozen soil (Morin clay) was determined in horizontally closed soil columns under temperature gradients. The flux of water migration was calculated from the water distribution curves before and after testing. The flux is directly proportional to the square rost of the test dwaston, and decreases with decreasing temperature and soil dry density.

CREEP AND STRENGTH BEHAVIOR OF FROZEN SILT IN UNIAXIAL COMPRESSION.

Zhu, Y., et al, July 1987, 67p., ADA-184 \$16. Refs. p.58-60. Carbee, D.L.

FROZEN GROUND MECHANICS, FROZEN GROUND STRENGTH, SOIL CREEP, STRESS STRAIN DIAGRAMS, RHEOLOGY, COMPRESSIVE PROPERTIES, TEMPERATURE EFFECTS, FROZEN GROUND PHYSICS, TESTS.

PROZEN GROUND PHYSICS, TESTS.

Uniaxial constant-stress and constant-strain-rate compression tests were conducted on more than 200 remoided, saturated, frozen specimens of Farthonks silt under various saturated. A series of curves of stress vs strain rate for various temperatures for strain rates ranging from about 0.00 to 1/100,000,000/s show a close strength correspondence between the constant-stress and constant-strain-rate tests. All of these "complete" stress vs strain rate curves could not be described by a single power law or exponential equation, indicating that different deformation mechanisms are dominant within different ranges of strain rate. Two critical strain rates for distinguishing between the different deformation mechanisms were observed to be near 1.1,000 and 1/1,000,000/s for the medium-dense frozen Fastbanks silt. The former indicates the transition from distrile failure to moderate brittle fracture as strain rate increases, while the latter indicates the transition from sistocation creep to glide creep (by the authors' definition). Based on the charges in fine law, two fundamental creeps were classified shortierm creep, which is governed by glide creep, and long-term creep, which is governed by glide creep. The failure strain was not sensitive to temperature and strain rate over a certain range of strain rates, but it was very resource strain was not sensitive to temperature and strain rate over a certain range of strain rates, but it was very sensitive to density. Assur's creep model (1990) for ice was used to fit the creep data in this study. It works well for short-term creep but does not fit as well for long-term creep. The rate process theory was applied to the commonders. A new both value of experimental activations. The rate percess theory was applied to the A very high value of experimental activation

energy was obtained for lower stresses, and a very high value of apparent activation energy was observed for higher temperatures. The peak compressive strength was very sensitive to temperature and strain rate byt relatively inconsitive to density. While the initial tangent modulus in not sensitive to strain rate, it increases with decreasing temperature and

MILITARY OPERATION, CHEMICAL PROPER-TIES, DROPS (LIQUIDS), SNOW COVER, ICE COVER, EVAPORATION, TEMPERATURE GRADIENTS, IMPURITIES.

GRADIENTS, IMPURITIES.
Literature concerning persistence of chemical warfare agents and related chemicals in cold coveronments is analyzed. An existing model of droplet persistence is discussed in relation to evaporation theory and practicel uncertainties. This model was questioned in the case of ice and some covered terrain—a new model may be needed, but the necessary experimental data for testing and validation are not yet available. Experimental evaporation data for chemicals on snow are needed as well as the solubilities of ice in the relevant chemicals. Since evaporation from ice is inferred to be significantly retarded, it was emphanized that the rates of chemical degradation need to be addressed under these conditions. Hydrolysis is a mechanism of agent diseptablish already experimentally demonstrated in ice. More experiments are needed under conditions realistically simulating agent dissensations on agent diseptation. Theoretical and indured experimental evidence suggest that it is a water pathway. Because thermal activation is theoretically not required, it may proceed equally rapidly at low received and indirect experimental evidence suggest that it is a wider pathway. Because thermal activation is theoretically not required, it may proceed equally rapidly at low of high temperatures. Suggestions for relevant experiments—despite evaporation and solubility tests, and tests of hydrolysis and photolysis of droplets on see and snow surfaces—are mode.

FRAZIL ICE, ICE WATER INTERFACE. SEASONAL VARIATIONS, GREENLAND SEA.
The physical properties of sea ice in the Fram Strait region
of the Greenland Sea were examined during June and July
1944 in conjunction with the MIZEX field program. Most
of the see sampled within Fram Strait during this period
was multi-year, it is estimated to ray dent at least 455
by volume of the total see discherged from Fram Strait
during Jance and July. Thickness and other properties
indicated that more of the multi-year see was older than
4 to 5 years. Soom cover on the multi-year see averaged
29 cm deep while that on first-year see was older than
30 cm deep while that on first-year see was older than
Much of the difference appears to be the result of enhanced
submittion of the snow on the thinner first-year see. The
samity profiles of first-year see clearly show the effects
of ongoing brine draining in that profiles from cores defled
inter in the experiment were substantially less saline than
earlier cores. Bulk associates of multi-year see are generally
much lower than those of first-year see. This difference
the time see types. This section examinations of crystal
structure indicate that should 15% of the see commend of
congestions see with typically columnate type crystal structure.
The remaining 25% committed of granular see with only a
few occurrences of snow see. The gravitar necessital
permantly of first, found in small amounts at the top of
See, but mainly observed in multi-year ridges where it
occurred as the more component of see in interfision wools.

EVALUATION OF THE MAGNETIC INDUC-TION CONDUCTIVITY METHOD FOR DE-TECTING FRAZIL ICE DEPOSITS

Arcone, S.A., et al, Sep. 1987, 12p., ADA-186 940, 13

Brockett, B.E., Lawson, D.E., Chacho, E.F.

ICE DETECTION, FRAZIL ICE, ICE GROWTH, ICEBOUND RIVERS, MAGNETIC SURVEYS, SUBGLACIAL OBSERVATIONS, WATER FLOW, MEASURING INSTRUMENTS.

MEASURING INSTRUMENTS.

The ability to map frazil ice deposits and water channels beneath an ice-covered river in central Alaska using the magnetic induction conductivity (MI) technique has been assessed.

The study was performed during the first week of Mar. 1986 on the Tanana River near Farbanks and employed a commercially available instrument operating at a fixed frequency with a fixed antenna (coil) spacing and orientation

Compansons of the MI data with theoretical models based upon physical data measured along three cross sections of the river demonstrate the sensitivity of the MI technique to frazil ice deposits. The conductivity generally derived for the frazil ice deposits encountered is very low (about 6.3 x 1/10,000 S/m) when compared with the measured value for gravel and sandy gravel bed sediments. In all three cross sections, maxims in the apparent conductivity profiles correlated with frazil ice deposits

In all three cross sections, maxims in the apparent conductivity profiles correlated with frazil ice deposits

Difficulties, possibly due to adverse effects of cold weather upon instrument calibration, affected the quantitative performance of the instrument on one cross section, although the interpretation of the data (locations of open channels vs frazil deposits) was qualitatively unaffected.

AUTOMATIC FINITE ELEMENT MESH GEN-

Albert, M.R., et al, Sep. 1987, 27p., ADA-186 939, 10 refs.

42-1518

HEAT TRANSFER, FLUID DYNAMICS, COM-PUTER PROGRAMS, MATHEMATICAL MOD-ELS. ENGINEERING.

Finite element computer codes are used in a variety of fields to solve partial differential equations of importance in science and engineering. The initial input to all of these programs requires the formation of a mesh (i.e. extensive these programs requires the formation of a mesh (i.e., extensive lists of geometrical data listed in particular orders), and the success of the solution depends on a well-formed mesh. This report documents a mathematical mapping technique and its implementation into a computer code that will automatically generate quality finite element meshes. This versatile generator uses standard FORTRAN, requires no special equipment (such as a digitizer), is very economical to run, and is user-friendly. The mathematical technique is discussed, advantages and limitations of the method are presented, examples are shown, and notes on user instructions are provided. provided.

APPROXIMATE SOLUTIONS OF HEAT CON-DUCTION IN A MEDIUM WITH VARIABLE PROPERTIES.

Y.-C., Sep. 1987, 18p., ADA-186 933, 6 refs. 42-1519

SNOW PHYSICS, HEAT TRANSFER, CONDUCTION, ANALYSIS (MATHEMATICS), HEAT BALANCE, THERMAL CONDUCTIVITY.

The approximate heat balance integral method (HBIM) is extended to the case of a medium with variable properties such as snow. The case of linear variation of thermal conductivity is investigated. An alternative heat balance conductivity is investigated An alternative heat balance integral method (AHBIM) is developed Both constant surface temperature and surface heat flux are considered A comparison is made of the temperature distribution from the HBIM, AHBIM and an analytical method for the case of constant surface temperature in general, results agree quite well with the analytical method for small values of dimensionless time fau, but the difference becomes more pronounced as tau increases. It is found that the AHBIM with a quadratic temperature profile gives a somewhat better result, especially when the value of the dimensionless distance is small. The results, when compared with those from HBIM, AHBIM and the analytical method are found to agree exceptionally well with the analytical method, especially for large values of tau. An alternative heat balance

MICROWAVE AND STRUCTURAL PROPERTIES OF SALINE ICE.

Gow, A J., et al, Oct. 1987, 36p., ADA-189 307, Refs.

Arcone, S.A., McGrew, S.G. 42-2419

ICE STRUCTURE, ICE SALINITY, MI-CROWAVES, ICE ELECTRICAL PROPERTIES, DIELECTRIC PROPERTIES, TESTS, TEMPERA-TURE EFFECTS, BRINES, MODELS, SEA ICE, STRUCTURAL ANALYSIS.

The structure and salinity characteristics of saline ice slabs removed from ice sheets grown in an outdoor pool have

been studied and related to the complex relative dielectric permittivity measured with free-space transmission techniques at 4.80 and 9.50 GHz. The saline ice closely simulated arctic sea ice in its structural and salinity characteristics, which were regularly monitored in a number of ice sheets grown during the winters of 1983-84 and 1984-85. Institu transmission measurements at similar frequencies were also made on the ice sheets themselves using antennas located above and beneath the ice. The slab measurements were made during warming from -29 to -2 C on slabs grown during the winter of 1983-84 (4.75 GHz) and during a warming and cooling cycle over a slightly larger temperature range on slabs grown during the winter of 1984-85 (4.80 and 9.50 GHz).

CR 87-21 MEASUREMENTS IN SPECTRAL TURBED BOUNDARY LAYER OVER SNOW. Andreas, E.L., Nov. 1987, 41p., ADA-190 217, Reis.

SNOW COVER EFFECT, SPECTRA, BOUNDARY LAYER, SURFACE TEMPERATURE, TURBU-LENT FLOW, HUMIDITY.

The author measured time series of longitudinal (u) and vertical (w) velocity and temperature (t) and humidity (q) fluctuations with fast-responding sensors in the near-neutrally vertical (W) velocity and temperature (I) and humidity (a) studies with fast-responding sensors in the near-neutrally stable surface layer over a snow-covered field. These series yielded individual spectra and u.w., w.q. and t-q cospectra, phase spectra and coherence spectra for nondimensional frequencies (fz/U) from roughly 0 001 to 10. This is, thus, one of the most extensive spectral sets ever collected over a snow-covered surface. With the exception of the u.w cospectra, all of the spectra and cospectra displayed the expected dependence on frequency in an inertial or inertial-convective subrange. All, however, contained significantly more energy at low frequency than the Kansas neutral-stability spectra and cospectra. This excess low-frequency energy and the erratic behavior of the u.w cospectra imply that the forested hills bordering the site on two sides were producing disturbances in the flow field at scales roughly equal to the height of the hills, 100 m. The phase and coherence spectra suggest that internal gravity waves were also frequently present, since the atmospheric boundary layer generally had slightly stable stratification. Consequently, at this complex site, turbulence alone determines the spectra and cospectra at high frequency; at low frequency the spectra and cospectra reflect a combination of topographically generated turbulence and internal waves. From the measured temperature and humidity spectra and the Leg cospectra. ed turbulence and internal waves from the measured temperature and humidity spectra and the 1-q cospectra, the author computed refractive index spectra for light of 0.55-micron and millimeter wavelengths, the first such spectra obtained over snow.

THERMAL INSTABILITY AND HEAT TRANS-FER CHARACTERISTICS IN WATER/ICE SYS-

Yen, Y.-C., Nov. 1987, 33p., ADA-189 627, 33 refs.

42-2420
ICE WATER INTERFACE, HEAT TRANSFER, MELTWATER, PHASE TRANSFORMATIONS, WATER TEMPERATURE, TEMPERATURE VARIATIONS, CONVECTION, ANALYSIS (MATHEMATICS), DENSITY (MASS/VOLUME), TEMPERATURE DISTRIBUTION.

This review discusses problems associated with the anomalous temperature-density relations of water. It covers a) onset of convection, b) temperature structure and natural convective heat transfer, and c) laminar forced convective heat transfer, and c) laminar forced convective heat transfer in the water/ice system. The onset of convection in a water/ice system was found to be dependent on thermal boundary conditions, not a constant value as in the classical fluids that have a monotonic temperature-density relationship. The water/ice system also exhibits a unique temperature distribution in the melt layer immediately after the critical Rayleigh number is exceeded and soon after it establishes a more or less constant temperature region progressively deepening as the melt layer grows. The constant temperature is approximately 3.2 C for water layers formed from above but varies for melt layers formed from below. The heat flux across the water/ice interface was found to be a weak power function and to increase linearly with temperature. This review discusses problems associated with the anomalous heat flux across the water/ice interface was found to be a weak power function and to increase linearly with temperature for melted layers from above and below, respectively. Both theoretical and experimental incling studies of ice spheres, cylinders, and vertical plates show a minimum heat flux in the water/ice system due to the density extremum of 4C. The inversion temperature was from 5.1 to 5.6 °C. For the case of laminar forced convection melting heat transfer, the presence of an interfacial velocity (due to phase transition) reduces heat transfer in comparison with the case without phase changes. without phase change.

AIRBORNE ELECTROMAGNETIC SOUNDING OF SEA ICE THICKNESS AND SUB-ICE BATH-

Kovacs, A., et al, Dec. 1987, 40p., ADA-188 939, 21

Vallcau, N.C., Holladay, J S

42-2551 ICE COVER THICKNESS, REMOTE SENSING, SEA ICE, ELECTROMAGNETIC PROSPECT-ING, SOUNDING, SUBGLACIAL OBSERVA-TIONS, AIRBORNE EQUIPMENT, ANALYSIS (MATHEMATICS).

A study was made in May 1985 to determine the feasibility of using an autoome electromagnetic sounding system for profiling sea ice thickness and the sub-ice water depth and conductivity.

The study was made in the area of Prudhoe conductivity. The study was made in the area of Prudhoe
Bay, Alaska. The multifrequency airborne electromagnetic
sounding system consisted of control and recording electronics Bay, Alaska sounding system consisted of control and recording electronics and an antenna. The electronics module was installed in a helicopter, and the 7-m-long tubular antenna was towed beneath the helicopter at about 35 m above the ice surface. For this electromagnetic system, both first-year and second-year sea ice could be profiled, but the resolution of ice thickness decreased as the ice became rough. This decrease was associated with the large footprint of the system, which effectively smoothed out the sea ice relief. Under-ice water depth was determined, as was seawater conductivity. The results of the feasibility study were encouraging, and further system development is therefore warranted.

OPTIONS FOR MANAGEMENT OF DYNAMIC ICE BREAKUP ON THE CONNECTICUT RIVER NEAR WINDSOR, VERMONT.

emieux, G.E., Weyrick, P.B., Demont, W.

ICE BREAKUP, ICE CONTROL, RIVER ICE, HY-DRAULICS, HYDROLOGY, FLOOD CONTROL, TESTS

TESTS

The Cormish-Windsor bridge is the longest covered bridge in the United States and has significant historical value. At a large peak flow, dynamic ice breakup of the Connecticut River can threaten the bridge and cause flood damage in the town of Windsor, VT. Throughout the 1985-86 writer we regularly monitored ice conditions, including a midwinter dynamic ice breakup on 27 January We conducted controlled release tests over the operating range of the turbines at Wilder Dam upstream during both open water and ice cover conditions. These data and observations were analyzed in light of more than 60 years of temperature and discharge records. Our analysis indicates that river regulation presents alternatives for ice management that would minimize the probability of bridge damage and flooding during breakup

FREEZING OF SOIL WITH AN UNFROZEN WATER CONTENT AND VARIABLE THERMAL PROPERTIES.

Lunardini, V.J., Mar. 1988, 23p, ADA-195 343, 15

SOIL FREEZING, UNFROZEN WATER CONTENT, THERMAL CONDUCTIVITY, PHASE TRANSFORMATIONS, TEMPERATURE EFFECTS, SPECIFIC HEAT.

FECTS, SPECIFIC HEAT.

While many materials undergo phase change at a fixed temperature, soil systems exhibit a definite zone of phase change. The variation of unfrozen water with temperature causes a soil system to freeze or thaw over a finite temperature range. Exact and approximate solutions are given for conduction phase change of plane layers of soil with unfrozen water contents that vary inearly and quadratically with temperature. The temperature and phase change depths were found to vary significantly from those predicts of or the constant-temperature or Neumann problem. The thermal conductivity and specific heat of the soil within the mushy zone varied as a function of unfrozen water content. It was found that the effect of specific heat is negligible, while the effect of variable thermal conductivity can be accounted for by a proper choice of thermal properties used in the for by a proper choice of thermal properties used in the constant-thermal-property solution

PERSISTENCE OF CHEMICAL AGENTS ON THE WINTER BATTLEFIELD. PART EVAPORATION FROM ICE AND SNOW. Leggett, D C., Mar. 1988, 10p., ADB-121 807, 17 refs.

MILITARY OPERATION, CHEMISTRY, EVAPORATION, SNOW IMPURITIES, ICE COMPOSI-TION SOLUBILITY, ICE AIR INTERFACE, TESTS

Very little information is available on the evaporation of liquid chemicals from ice or snow Organophosphorus chemical agents and their simulants have appreciable mutual solubility with water. Theoretically, this would be expected to lead to simple dilution, causing retardation of their evaporation at the ice/air interface. Polar chemicals such as these are also known to spread when applied to ice enhancing evaporation due to surface area expansion or a "spread factor" relative to non-spreading droplets. These notions were tested by comparing evaporation of dimethyl methylphosphonate (DMMP) from ice and Teflon, a non-spreading surface. Evaporation from ice was initially much slower, but increased with time, while the evaporation rate from Teflon was nearly constant. The data suggest that dissolution of ice at the interface retards DMMP evaporation. This is supported by the equilib, um solubility of ice in DMMP, which was measured concurrently. These preliminary results imply that evaporation of chemical agents dispersed on ice will be retarded to some degree by the dissolution process. Further experimentation will be needed to explain the observed increase in evaporation rate with time. Very little information is available on the evaporation of

COMPOSITE BUILDINGS FOR MILITARY

Flanders, S.N., Mar. 1988, 25p., ADA-194 475, 4 refs.

MILITARY FACILITIES, BUILDINGS, SAFETY, COST ANALYSIS, CONSTRUCTION MATERI-

ALS.

This report compares the use of composite buildings with the use of combine into fewer buildings. Composite buildings are those that combine into fewer buildings several uses that traditionally have occurred in separate buildings. The comparisons are based on construction costs, life cycle costs, speed of construction, materials availability, energy efficiency, fire safety, organizational efficiency, incremental or modular construction, and habitability. The uses reported on include a military training facility in St. Jean, Quebec, a shopping and community center complex for Fort Wainwight, Alaska, and battalion and brigade buildings for mobilization at Fort Leonard Wood, Missouri, and in Alaska. In each case, when comparisons are made between permanently constructed buildings, the composite buildings are cheaper to build and maintain than the conventional buildings. The composite buildings consume less energy and are much more convenient to their occupants.

MECHANICAL PROPERTIES OF MULTI-YEAR SEA ICE. PHASE II: ICE STRUCTURE ANAL-

Richter-Menge, J.A., et al, Mar. 1988, 27p, ADA-213 043, 15 refs.

43-4593

SEA ICE, ICE MECHANICS, ICE STRUCTURE, GRAIN SIZE, ICE COMPOSITION

GRAIN SIZE, ICE COMPOSITION

This report describes the structural analysis of multi-year sea ice samples that were tested in the second phase of a program designed to obtain a comprehensive understanding of the mechanical properties of multi-year sea ice from the Alaskan Beaufort Sea. Each test specimen is classified into one of three major ice texture categories granular, columnar or a mixture of columnar and granular ice. The crystallographic orientation, percent columnar ice, and grain size are then evaluated for the granular and/or columnar ice in the sample. Test results are interpreted with respect to these parameters. The overall composition of multi-year ridges is considered, based on the extensive field sampling that was done in the program. The effect of sample orientation on the results is also discussed.

This report presents results of small beam testing conducted This report presents results of small beam testing conducted in a test tank on ice corresponding in structure to the two major ice types, \$1 and \$2\$, encountered in lake ice sheets. Tests of 730 beams in the temperature range -10 -19 C showed that macrocrystalline (\$1) and columnar (\$2\$) ice differ appreciably in their flexural characteristics, and that these differences are attributable to variations in the size and orientation of the crystals in the ice and the thermal condition of the beams. Parallel testing of cantilever and simply supported beams indicated a virtual non-dependence of flexural strength on the temperature of the fiber in tension. It was also determined that the sharply terminated corners of conventional cantilever beams are a source ence of flexural strength on the temperature of the fiber in tension. It was also determined that the sharply terminated corners of conventional cantilever beams are a source of appreciable stress concentration that can reduce the intrinsic flexural strength by as much as one-half, but which, in most cases, can be substantially relieved by drilling holes at the beam roots. Overall, flexural strengths did not exceed 1200 kPa for cantilever beams or 1650 kPa for simply supported beams tested in parallel with cantilever beams. The highest flexural strengths were measured on isothermal simply supported beams of S2 ice tested with the top surface in tension, with average strengths for such ice increasing from 1650 kPa at -1 C to nearly 2600 kPa at -19 C -19 C

This report describes the development of a river ice prow to be attached to a towboat for opening ice-free navigation channels or for ice management in the vicinity of the locks and dams on the northern rivers of the United States (Illinois, Ohio and Upper Mississippi rivers) Following a literature construction and maintenance costs

Three successive models were constructed and tested in level ice in the CRREI. construction and maintenance costs. Three successive models were constructed and tested in level ice in the CRREL Test Basin to optimize the prow's performance from the points of view of resistance and maneuverability in level ice. Test results are presented and discussed.

MEASUREMENT AND INTERPRETATION OF ELECTRICAL FREEZING POTENTIAL OF

Kelsh, D.J, et al, Aug. 1988, 9p., ADA-201 699, 23 refs.

Taylor, S.

43-1562

FREEZING POTENTIAL (ELECTRICAL), FROST HEAVE, SOIL FREEZING, CHEMICAL COMPO-SITION, SOIL WATER, SOIL PRESSURE, EX-PERIMENTATION, ELECTRICAL PROPERTIES PERIMENTATION, ELECTRICAL PROPERTIES
When soil freezes, abrupt changes occur in the electrical
potential measured between electrodes buried in frozen vs
unfrozen regions. These "freezing potentials" can vary
in polarity and magnitude depending on soil type, freezing
rate, nature and concentration of electrolytes in the soilwater, etc. This report finds that electrical potential changes
of the same order of magnitude as freezing potentials (i.e.,
about 100 mV) can be generated by simply compressing
the soil at room temperature. This suggests that a significant
and previously unrecognized source of electrical freezing
potential could be due to pressure induced during frost heaving
Because many interrelated variables are responsible for electrical freezing potential, the use of freezing potential to predict cal freezing potential, the use of freezing potential to predict corrosivity, water migration, or other physical properties of freezing soils is considered to be inappropriate

ICING, ANTENNAS, ICE DETECTION, SYNOP-TIC METEOROLOGY, MOUNTAINS, ICE AC-CRETION, STATISTICAL ANALYSIS, ATMO-SPHERIC PRESSURE, MEASURING INSTRU-MENTS.

MENTS.
Statistics and weather maps are used to compare the atmospheric icing climatology of two New England mountains Mount Mansfield in northern Vermont and Mount Washington in New Hampshire. Atmospheric icing, as measured with Rosemount ree detectors, is twice as frequent on Mount Washington, with about 12-20 times greater intensities and 25-50 times more accretion. Periods between icing events average 35-45 hours on the two peaks. Most Mount Mansfield icing events are of low intensity. Plots indicate the return probabilities of ice events by length, intensity and accretion magnitude. Approximately half of all severe cing on the two peaks occurs during and immediately after cold front passages. Icing is most intense when lows are about 450 km to the east of the mountains. High-ressure centers are never closer than about 450 km during intense icing. Prolonged accretion periods occur when coastal and inland storms merge or follow closely.

SEA ICE, ICE MECHANICS, ICE SALINITY, ICE STRENGTH, ICE TEMPERATURE, ICE MOD-ELS, ICE DEFORMATION.

ELS, ICE DEFORMATION.

In many sea uce engineering problems the uce sheet has been assumed to be a homogeneous plate whose mechanical properties are estimated from the bulk salinity and average temperature of the ice sheet. Typically no regard has been given to the vertucal variation of ice properties in the uce sheet or to the time of uce formation. This paper first reviews some of the mechanical properties of sea ice, including the ice tensile, flexural and shear strengths, as well as the ice modulus. Equations for these properties are given as functions of the ice brine volume, which can be determined from the ice salinity and temperature. Next a numerical, finite difference model is developed to predict the salinity and temperature profiles of a growing ice sheet. In this model ice temperatures are calculated by performing an energy balance of the heat fluxes at the ice surface. The conductive heat flux obtained from the energy balance is then used to calculate the rate of ice growth and ice thickness by applying the Stefan ice growth equation. Ice salinities are determined by considering the amount of initial salt entrapment at the ice/water interface and the subsequent brine drainage due to brine expulsion and gravity drainage least only an experiment of the central Arctic Basin. The profiles appear to be realistic and agree reasonably well with field data. Finally the predicted salinity and temperature profiles are combined with the mechanical property data to provide mechanical property profiles for first-year sea ice of different thicknesses, grown at different times of the winter. The predicted profiles give composite plate properties that are significantly different from bulk properties obtained by assuming homogeneous plates. In addition with failure strength, profiles give maximum strengths in the interior of the sheet as contrasted vith the usual assumption of maximum strength at the cold, upper ice surface. Surprisingly the mechanical property profiles are only a function of the ince thickness, i In many sea ice engineering problems the ice sheet has

ICE GROWTH, COMPRESSIVE PROPERTIES.
This report presents a general discussion of model testing of ships in level (see The main points covered are: 1) modeling criteria for ships in ice, which must take into account the presence of a solid boundary at the water surface; 2) types of model ice used in various tanks—saline ice, urea-doped ice, EG/AD/S ice and synthetic ice; 3) techniques for growing model ice sheets, and achieving and monitoring the required ice properties, 4) limitations of both model ice and property measurement techniques. 5) model testing procedures for EHP and SHP tests and their limitations; 6) comparison between model test results and available full-scale trials data; 7) existing empirical and analytical or semi-analytical algorithms for predicting ship performance in level: 6) current research at CRREL and research facilities to improve modeling techniques and data interpretation, and 9) novel bow designs for ice-transiting vessels.

CHEMICAL ASPECTS OF SOIL FREEZING. Henry, K, Oct. 1988, 8p, ADA-205 392, 17 refs.

SOIL FREEZING, SOIL WATER, FROST HEAVE, FREEZING POINTS.

PREEZING POINTS.

Soil water chemistry and soil particle characteristics directly and significantly influence the freezing process in soils. The rate of frost heave is influenced because chemicals modify water migration and depress the freezing point in soils. Solutes are concentrated when they are expelled from crystallizing ice, modifying adsorbed film thicknesses, depressing freezing points, creating concentration gradients, altering forces between particles or between ice and particles, and modifying the chemical potential of the water. These effects often have counteracting influences on frost heave. Solute expulsion during freezing produces a "fringe-like" freezing front in saline soils, primarily because of freezing point depression; this may also be true in "nonsaline" soils. Heave can be reduced by adding chemicals to soil to depress the freezing point or to modify the soil's structure or hydraulic characteristics. The concentration of solutes in the unifrozen water of the freezing soil can possibly be used for isolating toxic wastes in soil.

CR 88-18 MEASUREMENT OF THE UNFROZEN WATER CONTENT OF SOILS: COMPARISON OF NMR AND TOR METHODS

Smith, M.W., et al, Oct 1988, 11p., ADA-203 082, 10 refs.

Tice. A R.

SOIL WATER, UNFROZEN WATER CONTENT. NUCLEAR MAGNETIC RESONANCE, DIELECTRIC PROPERTIES, FROZEN GROUND, TESTS, PHOTOMETERS, MEASURING INSTRU-MENTS

The results of a laboratory testing program, carried out to compare two independent methods for determining the unfrozen water content of soils, are described. With the to compare two independent methods for determining the unifozon water content of soils, are described. With the time domain reflectometry method, the unifozon water content is inferred from a calibration curve of apparent delectric constant vs volumetric water content, determined by experiment. Previously, precise calibration of the TDR technique was hindered by the lack of a reference comparison method, which nuclear magnetic resonance now offers. This has provided a much greater scope for calibration, including a wide range of soil types and temperature (unfrozen water content). The results of the testing program yielded a relationship between dielectric constant and solumetric unifozen water content that is largely unaffected by soil type, although a subtle but apparent dependency on the texture of the soil was noted. It is suggested that this effect originates from the lower valued dielectric constant for adsorbed soil water. In spite of this, the general equation presented may be considered adequate for most practical purposes. The standard error of estimate is 0.015 cu cm'eu cm, although this may be reduced by calibrating for individual soils.

Brief guidelines on system and probe

design are offered to help ensure that use of the TDR method will give results consistent with the relationship

ANALYSIS, TEMPERATURE EFFECTS, SOIL
STRUCTURE, TESTS, WATER CONTENT.

Unfrozen water content as a function of temperature was measured in the laboratory using nuclear magnetic resonance (NMR) for 16 undisturbed frozen cores acquired from the Northwest Alaska Pipeline Company Chilled Gas Test Facility. The cores were then remolded and brought to their original densities and water contents, and unfrozen water content densities and water contents, and unifozen water content as a function of temperature was again measured over three warming and cooling cycles It was found that differences in unfrozen water contents between the undisturbed warming and cooling curves depended upon relative degree of saturation and its effect on soil structure. Only slight changes occurred during the three warming curves of the remolded soil, indicating minor freezing and thawing consequences on the soil structure.

CR 88-20 DEVELOPMENT AND DESIGN OF SLUDGE FREEZING BEDS.

Martel, C.J., Dec. 1988, 49p., ADA-213 086, Refs. p.43-46. 43-4597

SLUDGES, SEWAGE TREATMENT, FREI THAW TESTS, MATHEMATICAL MODELS.

THAW TESTS, MATHEMATICAL MODELS.
This study develops design enteria for a new sludge dewatering unit operation called a sludge freezing bed. This bed uses natural freeze-thaw to condition the sludge. The total depth of sludge that can be frozen, thawed and dewatered by this process in a year is the main enterion needed for design. Laboratory tests assessed the dewaterability of freeze-thaw conditioned water treatment plant sludge and both anaerobically and aerobically digested wastewater sludges at various depths. Mathematical models for predicting the design depth were developed; values for the input parameters to the models were obtained from the literature or from laboratory and pilot-scale experiments. The dewaterability tests indicated that the depth of sludge that can be applied is not limited by drainability. Up to 20 m of each sludge drained in minutes after freeze-thaw conditioning Except for the aerobically digested sludge, the solids content each studge drained in minutes after treeze-inaw conditioning Except for the aerobically digested studge, the solids content after drainage is high enough to permit mechanical removal The physical and thermal characteristics of frozen studge were found to be equivalent to those of ice. An analysis of the freezing and thawing models reveals that the design of a freezing bed will depend on the duration and intensity of the freezing and thawing seasons.

MEASUREMENT OF FROST HEAVE FORCES ON H-PILES AND PIPE PILES.

Johnson, J.B., et al, Dec. 1988, 49p., ADA-205 010,

Refs. p.33-34. Buska, J.S.

FROST HEAVE, MEASUREMENT, PILES SHEAR STREES, ANALYSIS (MATHEMATICS).

SHEAR STRES, ANALYSIS (MATHEMATICS). The magnitude and variation of forces and shear stresses, caused by frost heaving in Fairbanks silt and the adfreeze effects of a surface ice layer and a gravel layer, were determined as a function of depth by using electric strain gauges along the upper 2.75 m of a pipe pile, 30.5 cm 1 D x 0.95 cm wall, and an H-pile, 254 cm web x 85 kg. lineal m. The peak frost heaving forces on the H-pile for three consecutive winter seasons (1982-1985) were 752, 790 and 802 kN, respectively Peak frost heaving forces on the pipe pile of 1118 and 1115 kN were determined only for the second and third winter seasons. Maximum average shear kN, respectively Peak frost heaving forces on the pipe pile of 118 and 1115 kN were determined only for the second and third winter seasons Maximum average shear stresses acting on the H-pile were 256, 348 and 308 kPa during the three winter seasons Maximum average shear stresses acting on the pipe pile were 627 and 972 kPa for the second and third winter seasons. Lee collars were placed around the tops of both piles during the first and third winter seasons to measure the adfreeze effects of a surface ice layer. The ice layer may have contributed 15 to 20% of the peak forces measured on the piles. A 06-m-thick gravel layer replaced the soil around the tops of both piles for the second and third winter seasons to measure the adfreeze effects of a gravel backfill. The gravel layer on the H-pile may have contributed about 35 of the peak forces measured. Maximum heaving forces and shear stresses occurred during periods of maximum cold and soil surface heave magnitude. These were not related to the depth of frost penetration for most of the winter since frost was present at all depths extending to the permafrost table. Soil surface displacements of 2 to 7 cm were measured at the experiment site during the study. The important mechanisms that determine the magnitude of uplift heave forces are 1) soil heaving as the driving force, and

2) soil temperature, which controls the unfrozen water content, mechanical properties of the soil and the area of influence of heaving pressure

BEAUFORT SEA.

Important and unique seabed engineering properties and conditions observed on the shallow shelf of the Beaufort Seamay be caused by low temperatures and variable salinities of bottom waters. A year-long monitoring program was initiated during the fall of 1985 to make daily measurements of these parameters using small, self-contained, low-cost instrumentation units placed on the seabed in 4 locations The 4 sites selected were in areas where overconsolidated sediments, seasonal seabed freezing and shallow ice-bonded permaffost are known to occur The instruments were recovered during the iall of 1986, 3 units contained useful data. The longest record was 341 days at station 8 in outer Harrison Bay. Seabed temperatures above 0 C, for the period of record, occurred only 15 days at one site and 13 days at another. The mean annual temperatures for these sites were -155 C and -160 C. Estimates of the onset of scabed freezing suggest that the seabed can freeze on all but 82 days of the year.

CR 89-02 AIRBORNE RADAR SURVEY OF A BRASH ICE JAM IN THE ST. CLAIR RIVER. Daly, S F, et al, Feb. 1989, 17p., ADA-206 868, 11

refs.

Arcone, S.A. 43-3475

ICE JAMS, AIRBORNE RADAR, RIVER ICE, SAINT CLAIR RIVER.

A brash ice jam in the South Channel of the St. Clair River was profiled in Feb 1987 using a helicopter-borne short-pulse radar operating in the UHF band near 500 MHz. During the same time, measurements of the brash ice depth and water temperature were made from a Coast Guard icebreaker. The returned radar pulses consisted of a strong coherent reflection from the water surface, preceded (and followed) by incoherent returns from the brash ice. The measured waveform time delays were then converted to mean freeboard height of the brash ice pieces above the water surface. Given the mean freeboard height, an estimate was greater than the range of the direct shipboard measurements. The difference is believed due to differences between ice porosity above and below the water line, to melting within the ice and to partial submergence of some of the surface; s. It is concluded that this technique could be used for mapping relative brash ice depth if the complexities of automating waveform analysis could be overcome.

INTERFACE, ANALYSIS (MATHEMATICS)

INTERFACE, ANALYSIS (MATHEMATICS)
The concepts of Gibbs free energy and surface tensions are deceloped to describe the state of water in two-phase porous soil systems in terms of the phis-variable. This approach differs from previous attempts at describing the thermodynamic behavior of water in porous materials by offering a simple and infutive framework. In this framework, the phis-variable is found to control the microscopic interfaces between the pore constituent ice or air and water.

INVESTIGATIONS OF DIELECTRIC PROPER-TIES OF SOME FROZEN MATERIALS USING RADIOWAVE CROSS-BOREHOLE TRANSMISSIONS

FROZEN GROUND, RADIO WAVES, DIELEC TRIC PROPERTIES, SITE SURVEYS, UNITED STATES-ALASKA

Pulsed radiowaves have been transmitted between boreholes at specially prepared sites in central Alaska to determine physical properties of the intervening material. The boreholes were drilled 12-25 m deep in both ice-rich sitt and frozen alluvium, materials commonly found in the Alaskan interior. The pulse spectra were centered near 100 MHz and were analyzed to obtain the ground dielectric constant and the attenuation rate (beta), which were then correlated with material type, water content and temperature. The ice-rich sitt, which had volumetric ice contents between 4 and 7 and beta values between 2 and 4 dB/m, thus limiting the use of our commercial equipment to borehole spacings of less thin 20 m. For this material, ground dielectric constant correlated well with volumetric ice content but not with temperature. In a deep section (25 m), dielectric contrasts were seen between 12 and 6 and beta values were less than 1 dB/m, thus allowing signals to be received at a borehole spacing of over 40 m. Generally, ground dielectric constant varied little with depth for any borehole pair. The pulses recorded at the widest spacing were due to direct transmissions and not to alternate, indirect with the meth timely surfed with the purch timelong were the surfer to the pulses recorded at the widest spacing were due to direct transmissions and not to alternate, indirect which the timelon timelong the pulse recorded at the widest spacing were due to direct transmissions and not to alternate, indirect which the direct and the pulse recorded at the widest spacing were due to direct transmissions and not to alternate, indirect which the direct and the pulse recorded at the widest spacing were due to direct transmissions and not to alternate, indirect which the direct and the pulse recorded at the widest spacing were due to direct transmissions and not to alternate, indirect which the direct and the pulse recorded at the widest spacing were due to direct transmissions and not to alternate, indirect which the differance and the Pulsed radiowaves have been transmitted between boreholes borehole pair The pulses recorded at the widest spacings were due to direct transmissions and not to alternate, indirect were due to direct transmissions and not to alternate, indirect paths that might include surface reflection or refraction. The observations thus demonstrate a method for reducing the number of boreholes commonly required for obtaining geotechnical information, and they provide data for determining borehole separation for a few common materials.

Delaney, A J., Calkins, D J 43-3477

AIRBORNE RADAR, RIVER ICE, SURVEYS, EN-VIRONMENTAL IMPACT

A helicopter-borne short-pulse radar survey was performed along the coastal plants of the Arctic National Wildlife Refuge in Mar. 1988 to help evaluate the potential environmental impact of resource exploration. The surveys

concentrated on the major rivers and a few lakes of the area and were performed at approximately 5-m altitude and 5-m/s flight speed. The radar antenna was externally mounted on the helicopter skids and emitted 6- to 7-ns pulses whose bandwich was centered near 500 MHz. The locations of most surveys were determined by a satellite positioning system. The ice cover was generally frozen to the river bed in all areas investigated, except for open water resets within extensive single, that developed downto the river bed in all areas investigated, except for open water reaches within extensive cings that developed downstream from hot springs. The reader data revealed subice water channels within the icings as well as water beneath the mound features in cing areas in the delta regions of the major rivers. A systematic radar survey, augmented with drilling, of one chain of three mounds allowed "be water volume to be estimated, but did not reveal any external source. It is speculated that a more intensive ground-based radar and drilling survey would clearly identify whether the water soruce was confined to the talik or was from an aquifer system. an aquifer system.

RUNWAYS, PAVEMENTS, FROST ACTION. DAMAGE, AIRPORTS, CRACKS In early fall 1984, a questionnaire was sent to over 325

In early fall 1984, a questionnaire was sent to over 325 general aviation airports in cold regions. The results from over 200 responses were compiled and evaluated and over 20 airport managers were contacted for additional details site visits were made to 16 airports to obtain additional information. The most common pavement problems identified in the study were associated with non-traffic-related phenomena and include 1) pre-existing cracks reflicting through asphalt concrete overlays (in two years or less) 2) thermal cracking, and 3) longitudinal cracking (at a construc-

tion io.nt) Most of the airports experienced 1) water pumping up through cracks and joints in the pavements during spring thaw, or 2) additional roughness due to differental frost heave in the winter, or both problems. Many airport managers reported that debris was generated at cracks during the winter and spring Many pavement problems can be traced to the evolutionary history of general aviation airports and the lack of consideration for site drainage. Based on the recognition of these problems, several future research programs are identified

CR 89-11 THERMAL AND SIZE EVOLUTION OF SEA SPRAY DROPLETS.

Andreas, E L., June 1989, 37p., ADA-210 484, Refs. 34-37 43-4042

DROPS (LIQUIDS), SEA SPRAY, MOISTURE TRANSFER, THERMODYNAMICS, BUBBLES, ANALYSIS (MATHEMATICS), MODELS.

ANALYSIS (MATHEMATICS), MODELS. Sea spray droplets initially have the same temperature as the ocean surface from which they formed. In high latitudes, under a relatively cold wind, they therefore cool and evaporate, in effect enhancing the air-sea exchange of heat and moisture. With a future goal of investigating this enhanced exchange in mind, this report develops model equations with which to track the thermal and size (moisture content) evolution of a spray droplet from the time it is created until it comes to equilibrium with its environment. On testing the model of a spray droplet from the time it is created until it comes to equilibrium with its environment. On testing the model against some of the scanty data available on the evolution of saline droplets, good agreement is found. The thermal evolution of the droplets obeys T(1)-T sub eq exp(-t/tau sub T) very well. Here, T is the instantaneous droplet temperature, T sub eq is the equilibrium temperature of the droplet and t is time. The time constant is the time required for the droplet to come to within 1/e of T sub eq. Similarly, for the moisture (size or radius) evolution, a time scale is defined as the time required for the droplet radius to come to within 1/e of its equilibrium radius. Tau sub r is always about three orders of magnitude larger than tau sub T, the thermal exchange is thus virtually complete before the moisture transfer starts. Consequently, the ambient humidity has little effect on the thermal exchange, and, analogously, the initial droplet temperature has negligible and, analogously, the initial droplet temperature has negligible effect on the moisture exchange.

CR 89-12 FRAMEWORK FOR CONTROL OF DYNAMIC ICE BREAKUP BY RIVER REGULATION.

Ferrick, M.G., et al, June 1989, 14p., ADA-210 869, 18 refe

Mulherin, N.

ICE BREAKUP, RIVER ICE, UNSTEADY FLOW, FLOOD CONTROL, ICE JAMS, ICE MODELS.

ICE BREAKUP, RIVER ICE, UNSTEADY FLOW, FLOOD CONTROL, ICE JAMS, ICE MODELS. In this report, we describe and classify the entire range of ice breakup behavior, from thermal to dynamic, to provide order to this complex process. The theory and model of the authors are refined, building on the concept of an intrinsic relationship between river waves and dynamic ice breakup. A force balance is developed for a common dynamic breakup behavior. Empirical criteria that quantify the resistance to breakup of an ice cover are obtained from a case study and compared with published values. Sensitivity studies of ice breakup with the completed model demonstrate insights that follow from the theory presented and the intuitive nature of the results. This framework for understanding river ice processes provides the option for ice management by river regulation, and we focus on the potential for control of ice breakup. The concept of controlled breakup models and that moves the ice downstream of locations with a high potential for damage during uncontrolled breakup. The abrupt, short-duration characteristics of the controlled release, patterned after those of unregulated river breakup, minimize both the volume of water required to cause breakup and the water levels at breakup. The open water created by the breakup collects heat that increases the rate of melting of the ice. The benefits of successful regulation include flooking prevention, minimum erosion, and decreased potential for ice damage to structures during breakup, without adverse effects on the convenience. decreased potential for ice damage to structures during breakup, without adverse effects on the environment. MAPPING, SUBSEA PERMAFROST, COASTAL TOPOGRAPHIC FEATUPES. ELECTRICAL RESISTIVITY, SOUNDING MODELS.

RESISTIVITY, SOUNDING MODELS.
Measurements were made at several New England coastal sites and at three sites in Prudh e Bay, Alaska, to evaluate de resistivity techniques for myping resistive scabed features bedrook and subsea permaffrest. The field studies employed the four-probe Wenner arrey technique, with electrode separations up to 50 m. The New England sites were selected to simulate permaffrest conditions to help establish a feeling for the range of apparent resistivity in areas of subsea permaffrest, and for information on the "tieal and lateral resolution of the technique. At Prudhoc 6ay, offshore measurements were made with a floating cible, and mland measurements were made using electrodisc diven into the ground. These observations indicate that the electrical properties of permafrost beneath the coastal bluff and adjacent tundra are rapidly

modified by coastal erosion and periodic flooding during storms. Maximum apparent resistivity at the water's edge was around 50 ohm m, and at distances greater than 100 m from shore all values were less than 20 ohm m Modeling m from shore all values were less than 20 ohm m. Modeling supported by the drilling data permitted an interpretation of the position of the top of ice-bonded subsea permafrost. Real resistivities for the ice-bonded permafrost ranged from 200 to 1000 ohm m. The technique and equipment used for this study appear to have applications for studies in shallow coastal waters where permafrost is not more than 30 m below the seabed and where water depths do not exceed 6 to 7 m.

DYNAMIC FRICTION OF A METAL RUNNER ON ICE. I. MODEL SLED TEST. Itagaki, K., et al, June 1989, 17p., ADA-211 498, 30

Huber, N.P., Lemieux, G.E.

SLEDS, METAL ICE FRICTION, ICE FRICTION, ICE SOLID INTERFACE, SKIS.

ICE SOLID INTERFACE, SKIS.

The effects of runner material and surface conditions on the friction between runners and ice were studied. A model sled was pushed over a 6-m-long ice sheet and the reduction of speed of the sliding sled was measured. The friction calculated by the reduction of speed between two gates indicated that smooth runners showed lower friction at around -1 C than at around -10 C, as expected, but the friction of rough runners showed little temperature dependence. The lower thermally conductive runner showed lower friction than higher thermally conductive smooth runners as the theory predicted, but such effects were obscured on rougher runners.

CR 89-15 TWO-STREAM CK 83-13 TWO-STREAM MULTILAYER, SPECTRAL RADIATIVE TRANSFER MODEL FOR SEA ICE. Perovich, D.K., July 1989, 17p, ADA-212 433, 24 refs.

SEA ICE, ICE OPTICS, ALBEDO, LIGHT TRANS-MISSION, ELECTROMAGNETIC PROPERTIES, RADIATION, MATHEMATICAL MODELS.

MISSION, ELECTROMAGNETIC PROPERTIES, RADIATION, MATHEMATICAL MODELS.

The reflection, absorption, and transmission of light at visible and near-infrared wavelengths is important for a number of geophysical problems. Light reflection is an important parameter in remote sensing studies, absorption is significant to ice thermodynamics, and transmission strongly influences biological activity in and under the ice. The focus of this report is on the reflection and transmission of light by spatially inhomogeneous and temporally varying sea ice covers. This is investigated using a two-stream, multilayer radiative transfer model in the wavelength region from 400 to 1000 nm. The model is computationally simple and utilizes the available experimental data on the optical properties of sea ice. The ice cover is characterized as a layered medium composed of selections from nine distinct snow and ice types. Three case studies are presented illustrating values of spectral albedo, transmittance, and transmitted photosynthetically active radiation (PAR) for 1) a spatially inhomogeneous ice cover. 2) a uniform ice cover as it undergoes a melt cycle, and 3) a temporally changing spatially variable incover. The importance of thickness and surface conditions on the reflected and transmitted radiation fields is demonstrated.

PHYSICAL AND OPTICAL PROPERTIES OF FALLING SNOW.

Koh, G, July 1989, 22p, ADA-212 432, 54 refs.

SNOWFALL, SNOW PHYSICS, SNOW OPTICS, MILITARY OPERATION, COLD WEATHER OPERATION, VISIBILITY.

The physical and the optical properties of falling snow have been investigated during a series of winter tests (SNOW experiments). The techniques for measuring the physical properties of falling snow are described and a review of the empirical and the theoretical models for describing the extinction of visible and infrared radiation by falling snow is presented. The utility of these findings for the evaluation of electro-optical sensor performance in a winter environment is examined.

CONTRAST AND VISIBILITY UNDER WINTER CONDITIONS WITH APPLICATION TO MO-TION DETECTION SYSTEMS.

Peck, L. Sep 1989, 8p., ADB-137 592, 21 refs 44-608

SNOW OPTICS, VISIBILITY, WARNING SYSTEMS, DETECTION, MILITARY EQUIPMENT, FOG, ANALYSIS (MATHEMATICS).

Video motion detection systems are used to automate the detection of intruders for physical security purposes. Wintertime conditions of fog and falling or blowing snow are likely to hinder the detection of objects by either an observer or a motion detection system. Theoretical equations of contrast and visibility are reviewed.

EVALUATION OF FOUR WELL CASING MATERIALS FOR MONITORING SELECTED TRACE LEVEL ORGANICS IN GROUND WA-

Parker, L.V., et al, Oct. 1989, 29p., ADA-216 502, 37

GROUND WATER, WATER POLLUTION, SOIL
POLLUTION, WELL CASINGS, MONITORS,
MATHEMATICAL MODELS, WATER CHEMISTRY, CHEMICAL ANALYSIS, ENVIRONMEN-TAL PROTECTION

In this study four well easing materials are examined, polyvinyl chloride (PVC), Teflon, stainless steel 304 (SS 304) and stainless steel 316 (SS 316), to determine their suitability for monitoring selected trace level organic constituents in stanless steel 316 (SS 316), to determine their suitability for monitoring selected trace level organic constituents in ground water. Analyte solutions containing pieces of the different well casings were compared to controls that did not contain any well casing material. The aqueous test solution contained approximately 2 mg/L of each of the following organic substances hexahydro-1,3,5-trinitro-1,3,5-triazine (RDX), trinitrobenzene (TNB), cis- and trans-1,2-dichlorethylene (CDCE and TDCE), m-introtoluer e (MNT), trichlorotehylene (CDCE, chlorobenzene (CDB, and o-, p., and m-dichlorobenzene (ODCB, and MDCB). Mercuric chloride was added to prevent biodegradation of the analytes. Two sets of isomers for DCE and DCB were selected to examine the effect of structure on sorption. Samples were taken after 0 hour, 1 hour, 8 hours, 72 hours, 7 days (168 hours), and approximately 6 weeks (1000 hours). There was no loss of any analyte in the samples that contained there type of stainless steel casing, although both types of casing rusted. The greatest losses were seen in samples that contained Teflon casings, especially for the chlorinated organics. Losses of PDCB and MDCB were the greatest, 16% and 18%, respectively, after only 8 hours. While losses were also observed for the samples containing PVC casing, the rate of loss was much slower, and usually 24 hours or more elapsed before losses were significant (more than 5%). After the 1000-hour samples were taken, the casings were rinsed and placed in clean vials containing fresh water and left for three days to allow for desorption. From both plastic casings measurable quantities of all the organics that had been lost from solution were recovered. fresh water and left for three days to allow for desorption. From both plastic casings measurable quantities of all the organics that had been lost from solution were recovered. We were able to correlate the loss of hydrophobic organic constituents in the ground water containing the Tellon casings with the substance's octanol-water partition coefficients, although this correlation overestimates losses of hydrophilic organics. The results indicate that Teflon casings are probably not suitable for monitoring trace level organics. For wells that are purged and sampled within an 8-to 24-hour period, PVC well casings probably are suitable for monitoring trace level organics.

DEVELOPMENT OF AN AIRBORNE SEA ICE THICKNESS MEASUREMENT SYSTEM AND FIELD TEST RESULTS.

Kovacs, A., et al, Dec. 1989, 47p., ADA-224-867, 23 refs.

SEA ICE, ICE COVER THICKNESS, ICE SUR-VEYS, AERIAL SURVEYS, RADIO ECHO SOUNDINGS, PRESSURE RIDGES, ICE ELEC-TRICAL PROPERTIES.

TRICAL PROPERTIES.

Recent efforts to improve airborne electromagnetic inductionmeasurement technology and to downsize the related helicopter-towed antenna assembly from about 7.5 m long to about
3.5 m long for use in airborne measurement of sea ice
thickness are discussed, as are the results from arctic field
testing. Also outlined are the system noise and drift
problems encountered during arctic field evaluation, problems
that adversely affected the quality of the sounding data.
The sea ice sounding results indicate that it should be possible
to determine thickness to within 5% to .ce floes with moderate
relief but that, because of sounding footprint size and current
model algorithm constraints, steep-sided pressure ridge keels
cannot be well defined. The findings also indicate that
routine sea ice thickness profiling from an airborne platform
is close at hand with further system improvement, as is
the apparent capability to determine the conductivity of
the sea ice, from which an assessment of sea ice strength
can be made can be made

ICE CONDITIONS ALONG THE ILLINOIS WA-TERWAY AS OBSERVED ON LANDSAT IM-

AGES, 1972-1985. Gatto, L.W., Dec. 1989, 112p., ADA-219 745, 11 refs.

ICE CONDITIONS, RIVER ICE, ICE SURVEYS, REMOTE SENSING, LANDSAT, UNITED STATES—ILLINOIS WATERWAY

Landsat images were used to map ice distributions along the navigable portions of the Illinois Waterway from the Mississippi River to Lake Michigan and air temperature and discharge data were used to characterize the conditions under which the observed ice formed and changed. The presence or absence of ice on adjacent water bodies i.e. lakes, channels and sloughs, is also discussed but not imapped. Ice was observed on the waterway during 10 of the 13

winters from 1972 to 1985, with the most severe ice conditions in 1981-82 when 79% of the waterway was ice covered, of which 68% was white ice on Feb. 4 The most extensive ice was observed during 1984-85 when 83% of the waterway was ice covered, but only 38% was white ice. Ice was observed on the adjacent water bodies every winter for about 100 days from early to mid-Dec to mid-Mar. Ice conditions changed frequently on the navigation channel of the waterway and usually lasted an average of 63 days from middle to late Dec. to middle to late Feb. Air temperature discharge data and data from Landsat images, when used together, provide a reasonably reliable method when used together, provide a reasonably reliable method to study river ice conditions and changes.

CR 97-12 ESTIMATING SEA ICE THICKNESS USING TIME-OF-FLIGHT DATA FROM IMPULSE RADAR SOUNDINGS.

Kovacs, A., et al, Dec. 1989, 10p., ADA-218 736, 1

Morey, R.M.

SEA ICE, DIELECTRIC PROPERTIES, RADIO ECHO SOUNDINGS, REMOTE SENSING, ICE FLOES, RADAR ECHOES.

FLOES, RADAR ECHOES.

Two second-year sea ice floes were probed using "impulse" radar sounding and direct drilling methods

The resulting two-way time of flight of the impulse radar EM wavelet, traveling from the surface to the ice "bottom" and back to the surface, was compared with snow and ice thickness data obtained from a drill hote

From this comparison, simple relationships are presented that provide an estimate of the thickness of sea ice, from about 1 to 8 m thick, with or without a snow cover. Relations are also presented that show the bulk or apparent dielectric constant of the sea ice decreased with inverteasing ice thickness from a value of about 7 for ice 1 m thick to about 35 for ice 6 m thick

THERMAL RESPONSE OF DOWNHILL SKIS. Warren, G C., et al, Dec 1989, 40p, ADA-219 279,

Colbeck, S.C., Kennedy, F.E.

SKIS, METAL SNOW FRICTION, THERMAL CONDUCTIVITY, SNOWMELT.

Large temperature increases were measured in donwhill skis A steady-state temperature was observed at the base, indicating that melting occurs over some portion of the base. This steady-state temperature increases with the ambient temperature and depends on ski speed and load, and the type of snow on the surface in the field measurements and in a finite element model of a Rossignol DH ski. In that particular ski, much heat propagates along an aluminum plate that connects with the steel edges of the ski. This combination about doubles the heat loss from the base and could reduce the thickness of the layer of lubricating meltwater, especially at lower temperatures. These large temperature increases provide further evidence of the existence of a layer of meltwater that would control the friction. The finite element model allows the predictions of material properties and geometry in the design of sliders for snow and tec. A steady-state temperature was observed at the base, indicating

CR 89-25 CHEMICAL AND STRUCTURAL PROPERTIES OF SEA ICE IN THE SOUTHERN BEAUFORT SEA.

Meese, D.A., Dec. 1989, 134p., ADA-219 746, 63 refs. For Ph.D. thesis of same title see 43-4573. 44-2630

SEA ICE, ICE COMPOSITION, ICE CORES, CHEMICAL ANALYSIS, SEA WATER FREEZING, BEAUFORT SEA.

ING, BEAUFORT SEA.

The purpose of this study is to provide a detailed chemical and structural profile of first-year and multiyear arctic sea ice. Ice cores were collected during Apr.-May 1986 and 1987 near Prudhoe Bay, AK. Concentrations of Cl. Br. SO4, Na. Aca, K. Mg. PO4, SIO4, NO3, NO2 and NH4 were determined for samples chosen on the basis of structural ice type. Chemical and statistical analyses indicate that finer-grained structures incorporate more impurities and that sailor in the ice indicating preferential drainage. Ratios of the major ions are the same for first-year and multiyear ice and are similar to that of seawater indicating that as the ice ages no significant changes occur in ice chemistry. Nutrient concentrations in the ice are enriched with respect to the underlying water, indicating that biological activity occurs in the ice and processes other than the overall salinity effect and brine drainage are affecting nutrient concentrations within the ice. within the ice.

CR 90-01 SIMULATION OF OIL SLICK TRANSPORT IN GREAT LAKES CONNECTING CHANNELS: THEORY AND MODEL FORMULATION. Shen, H.T., et al, Feb. 1990, 29p., ADA-222 446, 54 refs.

OIL SPILLS, COMPUTERIZED SIMULATION,
RIVER FLOW, MATHEMATICAL MODELS, ICE
COVER EFFECT, LAKE EFFECTS, ENVIRONMENTAL IMPACT, CHANNELS (WATERWAYS), GREAT LAKES.
The growing concern over the impacts of oil spills on aquatic
environments has led to the development of many computer
models for simulating the transport and spreading of oil
slicks in surface water. Almost all of these models were
developed for coastal environments. In this study, two
computer models, named as ROSS and LROSS, were developed
for simulating oil slick transport in rivers and lakes, respectively. The oil slick transformation processes considered in
these models include advection, spreading, evaporation and
dissolution. These models can be used for slicks of any
shape originated from instantaneous or continuous spills in
rivers and lakes with or without ice covers. Although
the study was originated by U.S. Army Corps of Engineers,
Detroit District in relation to the Great Lakes limited navigation season extension study, these models can be used for
any river and lake.

THREE FUNCTIONS THAT MODEL EMPIRICALLY MEASURED UNFROZEN WATER CONTENT DATA AND PREDICT RELATIVE HYDRAULIC CONDUCTIVITY.

Black, P.B., May 1990, 7p., ADA-223 875, 22 refs.

SOIL FREEZING, UNFROZEN WATER CONTENT, SOIL WATER MIGRATION, MATHEMATICAL MODELS, FROZEN GROUND.

EMATICAL MODELS, FROZEN GROUND. Empirically determined data on changes in unfrozen water content, occurring as result of changes in the state of ice and water in soil, are discussed with reference to the changes in soil-water retention data for ice-free soil. The similarity between the two types of data is developed The Brooks and Corey, van Genuchten and Gardner equations are then shown to be applicable to describing unfrozen water content data. These three functions are then used in the model of Mualem, and the relative hydraulic conductivity of frozen soil is predicted.

THERMOINSULATING MEDIA WITHIN EMBANKMENTS ON PERENNIALLY FROZEN SOIL.

Berg, R.L. May 1976, 161p, ADA-062 447, Ph.D. 120 refs. 32-1239

EMBANKMENTS, THERMAL INSULATION, PERMAFROST PRESERVATION, PROTECTIVE COATINGS, SOIL STABILIZATION, MATH-EMATICAL MODELS.

EMATICAL MODELS.

Most transportation facilities proposed for arctic and subarctic regions will be constructed on embankments. Incorporation of a thermonisulating layer within the embankment may permit use of reduced quantities of embankment material. Thermal design and analysis procedures applicable to embankments are reviewed and a two-dimensional numerical method coupling heat and mass transfer and vertical displacement is proposed. The modified Berggere equation, a method developed by Lachenbruch, and a finite difference technique are used to illustrate design and analysis methods for insulated embankments on permafrost. Most applications of insulation have been in seasonal frost areas but a few test sections have been constructed on permafrost. Stability of thermal and physical properties is a desirable characteristic of thermonisulating layers. Moisture absorption causes increased thersulating layers. Moisture absorption causes increased thermal conductivity and degradation of strength of some insulating materials. Several types of moisture barriers have been used but the most successful have been polyethylene sheets

SR 76-04 CREEP THEORY FOR A FLOATING ICE

Nevel, D.E., June 1976, 98p. ADA-026 122, 73 refs.

FLOATING ICE, ICE CREEP, LOADS (FORCES). STRESSES, ICE MECHANICS, MATHEMATI-CAL MODELS

The problem investigated is the prediction of the deflection and stresses in a floating tee sheet under loads which act over a long period of time. A review of analytical methods for predicting the bearing capacity of an ice sheet is given. The problem is formulated by assuming the ice is isotropic with a constant Poisson's ratio. The shear modulus is

assumed to obey a linear viscoelastic model. The specific model selected is a series of one Maxwell model and two Voigt models. One of the Voigt models has a negative spring constant which produces tertiary creep. The ice model exhibits a primary, secondary, and tertiary creep response, similar to that observed in uniaxial creep tests of ice. The material properties in the viscoelastic model may be a function of the vertical position in the ice sheet, but all these material properties must be proportional to the same function of position. Using the thin-plate theory for the floating ice sheet, the solution is obtained for the effection and stresses in the ice sheet for primary, secondary, and tertuary creep regions. It is then shown that for a load that is not distributed over a large area, the time-dependent part of the deflection and stresses is relatively independent of the load's distribution. For the elastic case, the stress significantly depends upon the load's distribute assumed to obey a linear viscoelastic model. The specific case, the stress significantly depends upon the load's distribu-tion Results are given for the deflection and stresses as a function of time and distance from the load. The maximum deflection and stresses occur at the center for the load. At this point the deflection increases with time, while the stresses decrease.

UTILITY DISTRIBUTION SYSTEMS IN ICE-

Aamot, H.W.C., May 1976, 63p., ADA-026 956.

UTILITIES, WASTE DISPOSAL, SEWAGE DIS-POSAL, SUBARCTIC LANDSCAPES, ICELAND. The study reports on new developments and special problems or solutions in water distribution systems, sewage collection systems, heat distribution and electric transmission system. Cold weather considerations are highlighted. For water and sewage transport, the use of ductile iron, concrete and plastic materials is reported. Utility lines are generally placed individually, utilidors are too expensive for most installations excent in some city center locations. placed individually, utilidors are too expensive for most installations except in some city center locations. Heat distribution with hot water from geothermal wells is mostly one-way piping. After heating, the water is discharged through the sewage system. Street heating is being expanded. With electric distribution, the use of self-supporting aerial cables is becoming popular because it is very cost-effective and reliable. Within the city, all distribution is under ground. Arcing of isolators on high voltage transmission lines due to salt from the ocean atmosphere is being reduced with silicone fluids.

INFLUENCE OF INSULATION UPON FROST PENETRATION BENEATH PAVEMENTS. Eaton, R.A., et al, May 1976, 41p., ADA-026 957, 10

Dukeshire, D.E. 32-1242

PAVEMENTS, SUBGRADE PREPARATION, FROST HEAVE, FROST PENETRATION, CEL-LULAR MATERIALS, THERMAL INSULATION. LULAR MATERIALS, THERMAL INSULATION. In order to minimize differential frost heaving caused by variable in-situ soil conditions, granular material is placed on top of the frost-susceptible subgrade. This creates a uniform layer to bridge subsurface irregularities in soil properties. This method of protecting the pavement structure can be costly. A method of reducing the amount of granular material is the use of a thermal insulating layer beneath all or part of the base course which prevents freezing temperatures from reaching the non-uniform subgrade. A test road which includes styrofoam board insulated test sections was constructed at CREEL in 1973. A transition section was built between a control section and an insulated section to minimize the drastic difference in frost penetration and resultant differential frost heave. Large temperature differences were measured between the insulated and conventional sections, frost penetrations were one-third as deep beneath the insulated section, differences in frost heave were negligible.

the insulated section, differences in frost heave were negligible. and pavement deflections were approximately the same on the two sections Surface differential leing did occur between the control and insulated sections

SKYLAB IMAGERY: APPLICATION TO RESER-VOIR MANAGEMENT IN NEW ENGLAND. McKim, H L., et al, Sep. 1976, 51p, ADA-030 329, 24

PHY, MAPPING, RESERVOIRS.
The purpose of this investigation was to determine the utility of Skylab S190A and B photography for providing reservoir management information in New England LANDSAT, Skylab S190A and S190B and RB-57, RCB images were reduced to a common scale of 163,360 for a marping base to demonstrate the extent to which the imagery could be utilized in the preparation of reconnaissance land use maps Visual interpretations were accomplished on original NASA

color infrared S190A/B and RB-57/RC8 transparencies and a LANDSAT false color print made in-house. Ancillary data were not used during the mapping exercise to eliminate bias in the comparisons and to ensure that the results were bias in the comparisons and to ensure that the results were derived strictly from interpretations of tones and textures on the photography. The classification scheme was a modified version of the U.S. Geological Survey Land Use Classification System for use with remote sensor data. The relative utility of the multiband imagery in identifying and quantifying hydrologic factors was evaluated. The land use statistics for two small watersheds were determined and the effects of these land use factors were appraised for possible contribution to runoff potential. This appraisal indicated that basin topography and the nature of runoff may be more important factors in predicting volume of runoff from a watershed than land use factors. Comparisons of the usefulness of the various imagery systems are made.

SURVEY OF ROAD CONSTRUCTION AND MAINTENANCE PROBLEMS IN CENTRAL ALASKA.

ENVIRONMENTS, HUMAN FACTORS ENGI-NEERING, BUILDINGS.

NEERING, BUILDINGS.

After classifying government environments in Alaska and studying four Federal Aviation Administration (FAA) and three Aircraft Control and Warning (AC&W) stations (in Phases 1 and 2), a cold regions environmental psychology behavior setting survey was made of Fort Wainwright, Alaska, to complete Phase 3. Phase 4 analyzed Fort Wainwright data and compared it with the FAA and AC&W data and previous studies The military locations could be characterized as temporary environments. The military environments differed from civilian environments in the behavioral areas of religion, government and professionalism FAA stations owere found to have the richest environment and AC&W stations compensated by providing greater leadership opportunities. Small stations the most deprived. Yet AC&W stations compensated by providing greater leadership opportunities. Small installations had an advantage over large installations in the participation level of their populations in recreational and other activities. Family housing, transient housing, barracks and work environments of Fort Wainwright were studied. Habitability guidelines were suggested for minimal renovation, major renovation and new construction of these kinds of buildings. An overall plan for a more habitable location of post facilities was suggested. The behavic setting survey technique in shortened form proved useful in this study. Suggestions for future research in testing habitability guidelines were made. SR 76-11 OBSERVATIONS ALONG THE PIPELINE HAUL ROAD BETWEEN LIVENGOOD AND THE YUKON RIVER.

32-1247

ROADS, SLOPE STABILITY, GROUND ICE, VEGETATION.

VEGETATION.

Periodic observations over a six-year period along the TAPS Road have been evaluated with respect to construction and slope stabilization techniques in ice-rich roadway cuts and embankment subgrades. Lateral drainage ditches of sufficient width to handle construction excavation equipment, along with near-vertical slope cuts with hand-cleared tops equal in width to one and one-half times the height of the cuts, significantly enhance natural processes of slope stabilization. Right-of-way clearing limited to the toe of embankment fill slopes minimizes subsidence of the roadway and its shoulder slopes. In extremely ice-rich soal cuts, the seeding of the slopes should not be attempted until late in the first thaw season for best results. Natural woody growth can be expected to have a substantial stabilizing effect after five or six thaw seasons but could be accomplished sooner by planting tree seedings. Attempts to stabilize ice-rich cut slopes with applications of insulation are not very effective and seem to prolong the natural stabilization process.

OPERATIONAL REPORT: 1976 USACRREL-USGS SUBSEA PERMAFROST PROGRAM BEAUFORT SEA, ALASKA.

Sellmann, P.V., et al, Oct. 1976, 20p., ADA-032 440,

Lewellen, R.I., Ueda, H.T., Chamberlain, E.J., Blouin, 32-1248

OFFSHORE DRILLING, LOGISTICS, SEA ICE, SUBSEA PERMAFROST.

SUBSEA PERMAFROST.

During the spring of 1976, three holes were drilled offshore in the Prudhoe Bay area using the sea ice cover as a drilling platform. The objectives of this program were to obtain samples and subsurface information to aid in quantification of the engineering characteristics of permafrost beneath the Beaufort Sea as well as to conduct supporting thermal and geological studies. The results of the drilling and related investigations are being used in conjunction with data from other subsea permafrost projects to develop maps and models for the prediction of permafrost occurrence in this offshore environment. The project also provides a means of testing drilling, sampling, and in-situ measurement techniques in an offshore setting where material types and sea ice conditions make acquisition of undisturbed samples extremely difficult. This report documents the operational aspects of the spring 1976 field study, subsequent reports will cover the technical and research results.

ENVIRONMENTAL ANALYSES IN THE KOOTENAI RIVER REGION, MONTANA. McKim, H.L., et al, Nov. 1976, 53p., ADA-033 500,

Gatto, L.W., Merry, C.J., Brockett, B.E., Bilello, M.A., Hobbie, J.E., Brown, J.

CLIMATOLOGY, RESERVOIRS, ICE COVER, LIMNOLOGY, SPACEBORNE PHOTOGRAPHY, UNITED STATES-MONTANA-KOOTENAL RIVER.

RIVER.

The purpose of this investigation was 1) to compile and analyze climatic data for the past 10 years from all available weather observing stations in the East Kootenai River Basin.

2) to analyze changes in ice and snow cover, and turbidity and plankton blooms on Lake Koocanusa, 3) to assess the present limnology of Lake Koocanusa and the potential for water quainty problems, especially eutrophication, and 4) to demonstrate the reliability of the LANDSAT Data Collection Platform (DCP)-Martek Water Quality Monitor system for acquisition of data from a remote site. Results of the investigations indicate that the Kootenai region is about twice as cold as the Libby region in winter, and that reservoir ice first forms along the shore in the northern region in alte November and in the southern part in mid-Deember, with total freeze-over usually occurring 2 to 4 weeks later lee break-up in the northern sections usually occurs 1-3 weeks later than in southern areas, average annual snowfall is 42 to 144 in, with ice thickness and snowfall varying with relief. Variations in areal distribution of snow within the basin and ice cover on the reservoir were effectively. is 42 to 144 m, with ice thickness and snowfall varying with relief. Variations in areal distribution of snow within the basin and ice cover on the reservoir were chiervable for periods from January to October 1973, and reservoir turbidity was observed to increase south of Ellsworth and Stenerson Mountains. Low algal productivity observed was due to the algae being circulated most of the time below the depth of 1% light and due to high Liribidity. The DCP-Martek system operated well and reliable lata were received while the system was located in the pool above Libby Dam and downstream below the dam. Brief interruptions in data transmissions occurred in April, when the Martek sensor showed a few minor inconsistencies, but the system demonstrated the feasibility of this technique for data acquisition from remote sites.

OIL SPILLS, SOIL TEMPERATURE, VEGETA-TION, PERMAFROST.

TION, PERMAPKOS1.

The long-term effects and ultimate fate of crude oil spilled on permafrost-underlain tundra is the subject of this study. The project involves two experimental oil spills of 2,000 gallons (7,570 liters) each on 500 sq m test plots near Fairbanks, Alaska. A winter spill, discussed in this progress report, took place in February 1976. Another spill will take place at the peak of the growing season in the summer This allows conditions prevailing during these climatic periods to be studied as to their effect on oil spills, and makes it possible to study the reaction of the spilled oil to these temperature extremes. The spill discussed in this report the possible to study the temperature extremes temperature extremes was designed to simulate a real pipeline leak, and was large enough to approach reality while remaining within the limits of logistical capabilities Monitoring of the spill and control plots includes: oil movement, temperature regime, biological effects, microbiological changes, permafrost impact, and chemical degradation of the oil.

UTILITY DISTRIBUTION SYSTEMS IN SWE-DEN, FINLAND, NORWAY AND ENGLAND. Aamot, H.W.C., et al, Nov. 1976, 121p., ADA-035 088, Bibliography p.116-121.

32-1276 ROOFS, MOISTURE, INSULATION, INFRARED EQUIPMENT.

Four building roofs at Pease AFB were surveyed with a hand-held infrared camera to detect wet insulation. Areas of wet insulation on these roofs were marked with spray paint, and 3-in diam core samples of the built-up membrane and insulation were taken to verify wet and dry conditions. Flashing defects are considered esponsible for most of the wet insulation uncovered in this survey. Recommendations for maintenance, repair, and replacement were developed from the infrared surveys, core samples and visual examinations.

ESTIMATING HEATING REQUIREMENTS FOR BUILDINGS UNDER CONSTRUCTION IN COLD REGIONS—AN INTERACTIVE COM-PUTER APPROACH.

Bennett, F.L., Feb. 1977, 113p., ADA-035 709, 65

COLD WEATHER CONSTRUCTION, BUILD-INGS, HEATING, HEAT LOSS, COMPUTER PROGRAMS.

The paper documents a review of construction literature to find reports of projects constructed under low-temperature conditions. A survey of Alaskan contractors to determine "cutoff temperatures" and other factors that cause suspension of various construction works is also presented. For both the literature search and the contractor survey, the lowest temperature mentioned was -70P. The paper also describes a computer program for estimating heat loss and enclosures and heating costs for buildings under construction in cold regions. The program is described, a sample program run is presented, and a successful validation effort is summarum.

HAINES-FAIRBANKS PIPELINE: DESIGN, CONSTRUCTION AND OPERATION.
Garfield, D.E., et al, Feb. 1977, 20p., ADA-038 445,

Ashline, C.E., Haynes, F.D., Ueda, HT.

32-1278
PIPELINES, MAINTENANCE, CONSTRUCTION, UNITED STATES—ALASKA.
This report is intended to provide a background for the analysis and evaluation of new pipelines being built in cold regions. Topics discussed include the initial design, construction, testing, operation and mignitenance of, and modifications to, the 8 in pipeline from the deep water port of Haines to multitary installations at Fairbanks, Alaska. The 626-mile multi-product pipeline began operation in 1956. The results of a corrosion survey completed in 1970 indicated that extensive renovation would be required to continue operations, and the section from Haines to Eiclson Air Force Base was closed in 1973

refs

ENVIRONMENTAL TESTS, HUMAN FACTORS ENGINEERING, BUILDINGS

ENGINEERING, BUILDINGS

A demonstration of Barker's k-21 test for identifying and differentiating behavior settings is presented as a means of diagnosing problems in an office environment. Couldelines for rearranging the layout of an organization so offices are developed that could also be used for architectural programming for a new building if the organization were to be reiocated. As an instructional program, the demonstration presented here shows how to conduct the k-21 test in order to analyze problems on crome behavior setting boundarorder to analyze problems concerning behavior setting boundar-ies or conflicts between behavior settings

SYMPOSIUM: GEOGRAPHY OF POLAR COUNTRIES; SELECTED PAPERS AND SUM-

Brown, J., ed, Mar. 1977, 61p., ADA-038 379, In English and Russian. Numerous refs. For selected pa-pers see 32-1302 through 32-1306. 32-1301

MEETINGS, LAND DEVELOPMENT, ENVI-RONMENTAL PROTECTION.

RONMENTAL PROTECTION.

The symposium on Geography of Polar Countries held in Leningrad 22-26 July 1976 as part of the XXIII International Geographical Congress consisted of three sessions. (1) Polar environment, natural resources, their exploration and exploitation; (2) Past, present and future economic developments in the polar regions; (3) Polar environment protection. This report presents the full text or extended summaries of a number of the U.S. papers, and English and Russian summaries of the Soviet contributions related to environmental protection.

The papers and summaries presented in this report reflect of the Soviet contributions related to environmental protection. The papers and summaries presented in this report reflect the participation of members and of the joint US-USSR environmental protection agreement project, Protection of Northern Ecosystems. The US papers deal with land use planning to mitigate environmental impact the impact of resource development on natives, fish and wildlife, and permafrost, the impacts of pipelines and roads on the environment, and computer modeling to simulate terrain modification due to man's activities. The Soviet summaries deal with subjects of properties and changes in arctic and subarctic flora, treeline, and permafrost, and methods of predicting changes in the environment.

SELECTED BIBLIOGRAPHY OF DISTURBANCE AND RESTORATION OF SOILS AND VEGETATION IN PERMAPROST REGIONS OF

THE USSR (1970-1976). Andrews, M., Mar. 1977, 116p., ADA-051 813.

BIBLIOGRAPHIES. CRYOGENIC REVEGETATION, LAND RECLAMATION.

REVEGETATION, LAND RECLAMATION.
The literature is discussed in chronological fashica, with general statements followed by highlights of each year's contributions (with three tables and two appendices for amplifications, and by 1975 there was a noticeable lag in pickup of publications by the indexing services. A trend is apparent from a reconnaissance and description approach in earlier papers toward an integrated ecosystem approach in more recent publications

Increased consciousness of the effects of disturbance on the permafrost environment, and the importance of restoration and preservation of these environments, are reflected in the recent literature, particularly in symposium proceedings

REVEGETATION AND EROSION CONTROL OBSERVATIONS ALONG THE TR PIPELINE—1975 SUMMER CONSTRUCTION SEASON.

Johnson, L.A., et al, Mar. 1977, 36p., ADA-038 416. Quinn, W.F., Brown, J.

32-1311 PIPELINES, SOIL EROSION, EROSION CONTROL, PROTECTIVE VEGETATION.

TROL, PROTECTIVE VEGETATION.

Procedures for revegetation and erosion control of the TransAlaska Pipeline System during the initial construction phase
are reviewed. Fertilizer and seed rates and schedules
of application by major areas (sections) are presented. During
the field season of 1975 CRREL personnel observed
revegetation and erosion control practices along the entire
length of the pipeline route. The types of problems and
early successes are discussed. Thirty-eight photographs
are presented of characteristic areas on which revegetation
was initiated. A list of sites for follow up observations
is presented. was initiated.

SR 77-09 INFRARED THERMOGRAPHY OF BUILD-INGS: AN ANNOTATED BIBLIOGRAPHY Marshall, S.J., Mar. 1977, 21p., ADA-038 447, 42 refs.

BIBLIOGRAPHIES. BUILDINGS. ANALYSIS, INFRARED RADIATION.

32-1312

ANALYSIS, INFRARED RADIATION. This report summarizes a review of the current literature on the new subject of infrared thermography of buildings. Infrared thermography of buildings. Infrared thermography of buildings (IRTB) uses a thermal imaging scanner to detect heat loss, structural defects, mosture, and other anomalies in building envelopes. Photographs of the imagery called thermograms provide hard copy documentation of faults detected. Thirty-four references are abstracted, covering research and development, roof mosture surveys, and qualitative/quantitative field surveys. The readily obtainable sources were chosen for their practical approach to providing potential users who are not scientifically oriented with an opportunity to quickly grasp the value of this new technology.

SR 77-10 COMPUTER ROUTING OF UNSATURATED FLOW THROUGH SNOW

Tucker, W.B., et al, May 1977, 44p., ADA-040 121. Colbeck, S.C.

SNOW COVER, WATER FLOW, SNOWMELT, COMPUTER PROGRAMS.

COMPUTER PROGRAMS.

Computer programs for routing the vertical movement of water through snow have been developed. The shock front is dependent on surface melt taking place now as well as the antecedent flow in the snow, usually a function of the nature of the flow for the previous day. One program, designed to accommodate actual surface melt data, has the ability to handle complicated input profiles such as when melt is erratic on a cloudy day, creating such complexities as intersecting shock fronts. Another program, designed for rapid simulation purposes, approximates a simple surface input with a function, in this case a sine wave. This function is easily changed, allowing a variety of conditions to be assessed, although only one shock front is accommodated. Error analysis and some applications of the programs are presented.

DEMONSTRATION OF BUILDING HEATING WITH A HEAT PUMP USING THERMAL EF-

Sector, P.W., May 1977, 24p., ADA-041 024, 13 refs. 32-1314

HEAT RECOVERY, HEATING, BUILDINGS, COST ANALYSIS, HEAT PUMPS.

COST ANALYSIS, HEAT PUMPS.

This report describes efforts made to recover waste heat and to reuse it to heat a building. A heat pump, which is a refrigeration device, was operated to provide building heat and to demonstrate both economic benefits and energy savings possible with this type of heating system. Heat pump fundamentals and system design considerations supplement the report of this demonstration project. Operational characteristics were monitored and are reported. A 25% reduction in heating costs was observed compared with an oil-fired system. The author recommends that the minimum coefficient of performance should be 3.4 for a cost effective, energy-conservative heat pump heating system.

LABORATORY STUDIES OF COMPRESSED AIR SEEDING OF SUPERCOOLED FOG. Hicks, J.R., et al, May 1977, 19p., ADA-040 633, 3

refs. Rice, R.C., Jr.

USSR—MAGADAN.

Two U.S scientists visited Kolyma Water Balance Station (KWBS) in Magadan Oblast of northeast USSR during the last two weeks of August 1976. Under the auspices of the Joint USA-USSR Agreement on Cooperation in the Field of Environmental Protection, this trip was undertaken to review current Soviet watershed hydrology research in a permafrost dominated setting similar to that of central Alaska. Research objectives, instrumentation, and field practices were observed and discussed at KWBS A series of proposals for future cooperation in high latitude hydrology research. for future cooperation in high latitude hydrology research and data exchange was prepared.

SR 77-16 COMPOSITION OF VAPORS EVOLVED FROM MILITARY TNT AS INFLUENCED BY TEM-PERATURE, SOLID COMPOSITION, AGE AND SOURCE.

Leggett, D.C., et al, June 1977, 25p., ADA-040 632,

Jenkins, T.F., Murrmann, R.P. 32-1319

EXPLOSIVES, IMPURITIES, VAPOR PRESSURE,

EXPLOSIVES, IMPURITIES, VAPOR PRESSURE, CHEMICAL ANALYSIS.

A number of domestic and foreign military TNT samples were analyzed by a gas chromatographic headspace technique. The method allowed the determination of the vapor pressure of TNT and the partial pressures of several associated impurities over a 2 to 32C temperature range.

A major volstile impurity in all U.S. military TNT samples was 2,4-dinitrotoluene, which had a partial pressure 1 to 2 orders of magnitude higher than the vapor pressure of TNT. The experimental data followed a Clausius-Clapeyron temperature dependence for the vapor pressure of TNT, and the partial pressure of DNT was related to its concentration in the solid by a Henry's constant.

Age and source of the TNT were found to have little or no influence on these relationships. The reasons for finding a relatively high DNT partial pressure are discussed, as is its implication for TNT detection by trace gas methods. trace gas methods.

SR 77-17 EFFECTS OF LOW-PRESSURE WHEELED VEHICLES ON PLANT COMMUNITIES AND SOILS AT PRUDHOE BAY, ALASKA.

Walker, D.A., et al, June 1977, 49p., ADA-041 593, 11 refs. Webber, P.J., Everett, K.R., Brown, J.

TUNDRA TERRAIN, DAMAGE, ALL TERRAIN VEHICLES, TIRES, TUNDRA VEGETATION, UNITED STATES—ALASKA—PRUDHOE BAY. An off-road vehicle test utilizing a smooth tired Rolligon weighing approximately 25,000 lb. was conducted at Prudhoe Bay, Alaska, on 25 June 1976. Vehicle impact on the vegetation and terrain was documented at 32 stations selected vegetation and terrain was documented at 32 stations selected as representative of the coastal tundra terrain. Twenty-seven stations were of single pass track and five were multiple pass lanes of up to 30 passes. The report documents the impacts with photographs and numerical ratings. Future observations will enable determination of rates of recovery

INSTALLATION OF LOOSE LAID INVERTED ROOF SYSTEM AT FORT WAINWRIGHT, ALASKA.

Schaefer, D., June 1977, 27p., ADA-041 574, 11 refs.

ROOFS, INSULATION, COST ANALYSIS.

ROOFS, INSULATION, COST ANALYSIS. In the summer 1971 the Corps of Engineers replaced the roof on Building 1033 at Ft. Wainwright, Alaska, with a loose-laid inverted roof system. This roof system was selected to permit an evaluation of its performance and potential suitability for general use in Corps construction. The installation of the roof also permitted an analysis of its construction crosts and a record of the construction procedures. Costs were identified in terms of costs of the materials used and the number of man-hours required. For the analysis, the job was broken down into four phases. I) removal of the existing roofing material and preparation of the deck, 2) application of a surface of plywood decking, 3) placement of the butyl membrane and installation of fashings, and 4) placement of the insulation and ballast pavers. The results show that the installation time requirements compare favorably with those of conventional builting roofs but the butyl membrane and the pavers cause higher material costs. Advantages are in the maintainability of the roof system and in its increased life expectancy.

SOIL ANALYSIS, SOIL CHEMISTRY, SLUDGES. PLANTS (BOTANY), VEGETATION.

PLANTS (BOTANY), VEGETATION.

A field study was conducted to assess the effects of sewage sludge and lime on the revegetation and reclamation of acidic (pH 3 0) and infertile dredge soils. Sewage sludge at 100 metric tons/ha and lime at 25 metric tons/ha were applied during the summer of 1974 on a seven hectare site and plowed into the soil to a depth of 20 cm. Soils were sampled 20 months after sludge incorporation at three depths, 0-20, 20-40, and 40-60 cm within the sludged and control areas. A total of 29 grass treatments, containing grasses seeded alone or in combinations, were also evaluated and seven grass types analyzed for mineral composition. Comparisons between the sludged and control areas in the layers from 0-20 cm and below 20 cm were made in terms of changes in soil and plant chemistry, plant utilization of soil minerals, plant adaptability and vigor, and eventual resulting vegetative cover.

SEA ICE, IMPACT STRENGTH, PENETRATION

In March 1970 drop penetrometer tests in sea ice were made by Sandia Laboratories for the U.S. Coast Guard In support of this study, properties of the sea ice penetrated were measured. The data collected included ice temperature, salinity, brine volume, density and Brazil tensile strength versus depth.

The data are presented in this report in both tables and graphs as a permanent data sou SP 77-25

SOLVING PROBLEMS OF ICE-BLOCKED DRAINAGE FACILITIES.

Carey, K.L., Aug. 1977, 17p., ADA-044 994, 4 refs. 32-1357

SURFACE DRAINAGE, ICE CONTROL, HEAT-ING. SUBSURFACE DRAINAGE.

ING, SUBSURFACE DRAINAGE.

The report summarizes several processes for ice formation and blockage in culverty, ditches, and subsurface drains. Solutions to ice blockage problems involve ice prevention and ice control, usually the latter. In some cases, culverts can be closed, leading to intentional ponding and storage of ice. Alternatively, flow can be maintained in culverts by heating them electrically, with steam, or with oil-burner heaters. Ditches can also be heated, but it is usually more effective to widen them to provide more storage space for ice, or to invitall insulating covers. Subsurface drain outlets can be heated, protected with insulating covers, or partially blocked to prevent cold air entry. Ground seepage that forms ice is successfully controlled using ice fences. Design changes, such as more and larger drainage structures, staggered culverts, and channel modifications, are discussed. SR 77-26 SR 77-26

INFRARED THERMOGRAPHY OF BUILD-INGS: QUALITATIVE ANALYSIS OF FIVE BUILDINGS AT RICKENBACKER AIR FORCE BASE, COLUMBUS, OHIO. Munis, R.H., et al, Sep. 1977, 21p., ADA-067 161.

INFRARED PHOTOGRAPHY, THERMAL DIF-FUSION, BUILDINGS, HEAT LOSS, WINDOWS.

An interior, infrared thermographic survey of single-pane, aluminum-frame, projected windows was performed to pinpoint locations of excessive infiltration. Infrared thermographic inspection accomplishes this more quickly and more accurately than conventional techniques of studying window infiltration. This report presents 32 thermograms and photographs which in many cases dramatically illustrate infiltrations around the in many cases dramatically illustrate infiltrations around the mullion, along the top opening cracks, and under the frame/sill interfaces. Poor glazing seals were easily detected and the exact points of glass/frame leakages were pinpointed. Plumes of warm air on the window glass, rising from the convectors, were dramatically captured by the infrared camera system. In several cases, the plumes were noted 12 ft. above the convectors on the top window panels. Heat loss from the convectors was noted through the walls of the building in the semerame take from the outside. Several the building in thermograms taken from the outside. Several recommendations were prepared for the General Services Administration, owner of this Federal Office Building in Burlington, Vermont.

PAVEMENT RECYCLING USING A HEAVY BULLDOZER MOUNTED PULVERIZER. Eaton, R.A., et al, Sep. 1977, 12p. + appends., ADA-

046 008, 8 refs. Garfield, D.E.

32-1361

EXCAVATION, SUBGRADES, PAVEMENT BASES.

Recycling of paving materials is currently gaining acceptance as a means of economic savings in pavement reconstruction or rehabilitation. Pavements having low serviceability indices due to surface irregulanties such as cracks, bumps, spalling, potholes, etc., may be broken up to meet specified granular base course gradation requirements and reused as a base for the new surface. The USACRREL developed a base for the new surface The USACRREL developed a permafrost excavating attachment for heavy buildozers and a prototype test rig was constructed.

Tests were conducted on frozen soils, gravels, and ledge this rig was used to pulverize a flexible pavement on North Main Street in Hanover, N H, and highway pavement test sections in a CRREL test facility The resultant processed material did meet Corps of Engineers base course gradation requirements. The machine can process 120 square ft of pavement structure per minute to a depth of 12 inches The most uniformly graded material was obtained at a drum speed of 15 revolutions per minute. Once the pavement structure is broken down from the solid mass (asphalt concrete pavement), the machine does not further break down or pulverize the aggregate. A minor amount of dust was evident during the operations, but no refinements are recommended mended

AERIAL PHOTOINTERPRETATION OF A SMALL ICE JAM.

DenHartog, S.L., Oct. 1977, 17p., ADA-045 870. 32-1362

ICE JAMS, AERIAL SURVEYS, PHOTOINTER-PRETATION

Acrial photos of a small ice jam on the Pemigewasett River near Plymouth, New Hampshire, were taken three days after the jam and compared with photos taken after the ice went out. The winter photos show a marked and sudden decrease out. In eviline photos show a marked and sudden decrease in floe size apparently indicative of faster and longer movement of the ice. The spring photos show a number of shallows and obstructions that apparently had no effect on the ice movement. It is concluded that this jam was caused by a change in slope and subsequent reduction in selectly

SR 77-33 LAND TREATMENT OF WASTEWATER AT WEST DOVER, VERMONT.

Bouzoun, J.R., Oct. 1977, 24p, ADA-046 300, 12 refs WATER TREATMENT.

WASTE DISPOSAL, W SEWAGE TREATMENT.

A general description of a wastewater land treatment system located in a "cold temperate" climatic region is given. The winter season average daily design now is almost double that of the summer-fall season (0.55 MGD vs 0.30 MGD) wastewater is sprayed on a forested knoll after it receives secondary biological treatment. The system is operated secondary biological treatment. The system is operated during the winter when the ambient air temperature is as low as 10F. Spray nozzles have been developed that ensure rapid drainage of the spray laterals after each spray cycle and, therefore, prevent their freezing

CANOL PIPELINE PROJECT: A HISTORICAL

Ueda, H.T., et al, Oct. 1977, 32p., ADA-046 707, 8

Garfield, D.E., Haynes, F.D.

PIPELINES, HISTORY, ARCTIC LANDSCAPES

PIPELINES, HISTORY, ARCTIC LANDSCAPES
This report is a historical review of the Canol project, the
first long-distance petroleum pipeline system constructed in
the Arctic region of North America. The project was
initiated during the early days of World War II when the
military situation appeared critical. It was designed to
supply the military need for fuel in the area, particularly
Alaska, by exploiting the Norman Wells oil field in the
Northwest Territory of Canada. The system was completed
in April 1944 and operated for II months converting 975,764
barrels of crude oil into gasoline and fuel oil. Construction
for the pioneering effort was difficult and costly. Considerable controversy plagued the project throughout, nevertheless,
its completion proved that undertakings of such magnitude
could be accomplished despite the formidable problems of
the Arctic.

SR 77-35

CEMENTS FOR STRUCTURAL CONCRETE IN COLD REGIONS.

Johnson, R., Oct. 1977, 13p., ADA-046 302, 19 refs

WINTER CONCRETING, CONCRETE ADMIX-TURES, CONCRETE STRENGTH, CONCRETE CURING, CEMENTS.

A literature search was undertaken to collect information on cements which could be used in structural concrete and would cure at low temperatures. In the literature search, 18 types of cements or concretes manufactured by various firms were reviewed. Trade names are identified with their cement or concrete description, temperature range for curing, use experience and application, approximate cost (in 1976), and reference source or manufacturer.

SMALL COMMUNITIES RESULT IN GREATER SATISFACTION: AN EXAMINATION OF UN-DERMANNING THEORY.

Ledbetter, C.B., Nov. 1977, 15p, ADA-046 817, 3

32-1367

HUMAN FACTORS, THEORIES.

HUMAN FACTORS, THEORIES.
Roger Barker's undermanning theory states that the smaller an organization, the greater the degree of undermanning, resulting in greater inhabitant satisfaction. This theory is examined using the National Opinion Research Center's General Social Survey for 1974. Two groups of survey variables were dichotomized and net transmittances or coefficients of correlation for the system were determined. Two groups of variables were chosen objective groups, such as age and income, and subjective ones, such as sociability and job satisfaction. The only positive correlation found was that people residing in small communities are more satisfied with their community than are people who live in large communities. Only a small portion of this is explained by the degree to which small town inhabitants are satisfied with their financial situation.

UTILIZATION OF SEWAGE SLUDGE FOR TER-RAIN STABILIZATION IN COLD REGIONS. Gaskin, D.A., et al. Nov. 1977, 45p., ADA-047 368 Hannel, W., Palazzo, A.J., Bates, R.E., Stanley, L.E.

SOIL STABILIZATION, SLUDGES, EROSION CONTROL, SEWAGE, VEGETATION.

CONTROL, SEWAGE, VEGETATION.
A terrain stabilization research/demonstration site was constructed in May 1974 at Hanoser, New Hampshire, to investigate various combinations of physical, chemical and biological techniques for terrain stabilization in cold regions. Fourteen test plots (10 x 40 ft) with individual 350 gal tanks to collect sediment were installed on a 16 deg slope. These 14 test plots were to examine the effectiveness of seage sludge and primary effluent on terrain stabilization in cold regions. In 19 of the 14 plots the variables studied were nutrient source (fertilizer, sludge, and primary wastewater), moisture (trigated and nonirrigated), crission control material fute netting, straw tacked with a tasking compound), in occision control material and segetation (three grasses and two legiumes). The control plot was left bare of seed,

fertilizer and erosion control material for compensation 20,000 sq ft area adjacent to the 14 plots was installed for general testing of various combinations of tacking chemicals, the control of the co plastic netting, straw, and wood fiber mulch. In general, all treatments with the exception of two plots were effective in reducing soil loss in comparison with the control which had a loss of 34,531 lb of soil (dry weight) on a per acre basis.

FINITE ELEMENT MODEL OF TRANSIENT HEAT CONDUCTION WITH ISOTHERMAL PHASE CHANGE (TWO AND THREE DIMEN-

Guymon, G.L., et al, Nov. 1977, 167p., ADA-047 369. Hromadka, T.V., II.

THERMAL CONDUCTIVITY, MATHEMATICAL MODELS, COMPUTERIZED SIMULATION, FROZEN GROUND MECHANICS, COMPUTER PROGRAMS.

The partial differential equation for transient heat conduction is solved by a finite element analog using a quadratic weighting function for the discretized spatial domain. The transient problem is solved by the Crank-Nicolson approximation. Two dimensional and three dimensional models incorporated Two dimensional and three dimensional models incorporated in the same computer program are presented element method is reviewed, assumptions and limitations upon which the model is based are presented, and a complete derivation of the system analog is included. Certain problems can only be modeled as a three dimensional system, e.g., thaw degradations around roadway culverts, embankment dams on permafrost where dam length is short relative to dam width, and thaw and freezeback under buildings. In most cases, however, the more economical two dimensional model can be used. Numerical tests of both models have been accomplished but field verification has not been attempted. A user's manual and a FORTRAN IV computer listing of the program are presented.

TEMPORARY PROTECTION OF WINTERTIME BUILDING CONSTRUCTION, FAIRBANKS, ALASKA, 1976-77.

Bennett, F.L., Nov. 1977, 41p, ADA-048 987, 2 refs. 32-2729

COLD WEATHER CONSTRUCTION, BUILDINGS, HEATING.

Nine building construction projects, whose total area exceeds one half million square feet, were under construction in Fairbanks, Alaska, area during the winter of 1976-77. These projects were studied to determine the methods used for projects were studied to determine the methods used to providing temporary enclosures and temporary building heating during the construction process. The types of construction activities underway at various temperature conditions are reported, and a record of temperature variations in the buildings. under construction is discussed. Both black and white and color photo documentation was developed, and several black and white photographs are included in this report

SR 77-40 VINTER EARTHWORK CONSTRUCTION IN

UPPER MICHIGAN. Haas, W M., et al. Nov 1977, 59p., ADA-049 052, 5 See also 32-293.

Alkire, B.D., Dingeldein, J.E.

EARTHWORK, SUBGRADE PREPARATION, COLD WEATHER CONSTRUCTION, FROZEN

Winter earthwork construction was observed in three counties in Michigan's Upper Peninsula during the 1975-76 season. In all cases, construction methods are used which exclude frozen soil from the central core of the embankment, with frozen soil permitted in the outer slope zone. While all projects were technically successful, construction was halted all projects were technically successful, construction was halted in early. February on one project because it was uneconomical for the contractor to continue. On another project, the contractor successfully exploited soil freezing to form stable smooth haul roads for his scrapers. Most of the work consisted of raising the grade of existing roads by 18 inches of non-frost-susceptible soil to minimize frost heaving and losts of bearing capacity. This winter activity resulted in better utilization of county equipment and work crews

Sellmann, P.V., et al. Dec. 1977, 19p., ADA-048 985. 11 refs See also 32-1248 (SR 76-12, ADA-032 440). Chamberlain, E.J., Leda, H. F., Blouin, S.E., Garfield. D.E. Lewellen, R.I.

12-2697 OFFSHORE DRILLING, DRILL CORP ANAL-

OFFSHORE DRILLING, DRILL CORP ANALYSIS, SUBSEA PERMAFROST, BOTTOM SEDI-MENT, TEMPERATURE MLASUREMENT During the spring of 19²⁰ soil samples were obtained in the Prudhoe Bay area from one hole drilled on land and five holes drilled offshore. The study is a continuation of the program started the previous season to examine the engineering characteristics and properties of permafrost under the Beaufort Sea. I imphasis was placed on establishing the range of thermal and physician properties found in this geological setting, which is thought to be common to much

of the eastern Alaska coastal zone. Twenty-seven probe sites were selected to determine local engineering properties of the eastern Alaska coastal zone. Twently-seven probestes were selected to determine local engineering properties and temperature conditions, and to aid in interpreting the lithology between the drill holes. Core drilling information from some of the probe sites was used as control for interpreting the probe records. Deep thermal and geological information was obtained from the drill sites by the USGS personnel participating in the study. Maximum drill hole depth was 68.5 m (225 ft) and maximum penetration depth was 15 m (50 ft). The probe temperature data indicated the presence of permaftost in all holes. Probe penetration resistance measurements helped to delineate shallow, techonded zones, some of which may have been only seasonal. In the core study, frozen sediments were found in only one hole, at approximately the 29 6-m (97-ft) depth. Fine-grained sediments were more common than course-grained material, and showed general increase in thickness with increasing distance from shore. The only departure from the previous year's field drilling techniques was the use of larger diameter, thick-walled easing and an air-operated casing driver. The probe equipment and techniques employed, however, represented a significant improvement over the prototype equipment used in 1976.

GROUTING OF SOILS IN COLD ENVIRON-MENTS: A LITERATURE SEARCH.

Johnson, R., Dec 1977, 49p., ADA-049 436, 52 refs. 32-2548 GROUTING, ADMIXTURES, SOIL STRENGTH.

A literature search was undertaken to collect information on grouting of soils as related to low temperature environment, 40 F and below This report reviews existing literature and the state-of-the-art on conventional grouting engineering methods and materials to seek which may be used in thawed or dry, frozen ground and to establish the need of new methods and techniques where conventional grouting methods

CREEL ROOF MOISTURE SURVEY, BUILD-ING 208 ROCK ISLAND ARSENAL. Korhonen, C., et al, Dec. 1977, 6p., ADA-051 490. Dudley, T., Tobiasson, W. 32-2730

ROOFS, MOISTURE, INFRARED RADIATION.

The roof of building 208 at Rock Island Arsenal was surveyed for wet insulation using a hand-held infrared camera Areas for wet insulation using a hand-held infrared camera. Areas of wet insulation were marked with spray point on the food and 3-in-diam core samples of the built-up membrane and insulation were obtained to verify wet and dry conditions. Roof defects uncovered during a visual inspection were also marked with spray paint. The majority of the wet areas detected are associated with flashing flaws, which are considered responsible for the wet insulation. Recommendations for maintenance of this roof are based on information derived from the infrared survey, core samples and visual examinations.

33-1528

OIL SPILLS, DAMAGE, CHEMICAL REACTIONS, FROZEN GROUND, ENVIRONMENTAL IMPACT, VEGETATION.

TAL IMPACT, VEGETATION.
This spill was compared with one that took place in February 1976 (reported upon in the first annual progress report). Oil moved downslope at a much faster rate during the summer spill than during the winter spill. In the winter he oil cooled and pooled rapidly. The summer spill covered approximately one-third more surface area than did the winter spill in the final configuration, even though the worspills were of almost identical volume. Increases in microbial populations and activities during the months following the spill were evident. Increased counts of bacteria, yeasts, dentitifying bacteria, and petroleum degrading bacteria following the spills were particularly evident. Analysis of oil decomposition using gas chromatography techniques indicated that the low molecular weight fractions, methane and ctane, were lost almost immediately after the spill in each case. Fractions in the C3 to C3 range were reduced significantly in two months and were nearly zero at the end of five months. An obsious adverse effect on vegetation was noted in both spills. Biological damage from the summer spill appeared to exceed that from the winter spill.

RECOMMENDATIONS FOR IMPLEMENTING ROOF MOISTURE SURVEYS IN THE U.S. ARMY.

U.S. Army CRREL, W.E.S. FESA Roof Moisture Research Team, Aug. 1978, 8p., ADB-031 978L, Distribution limited to U.S. Government agencies only

MOISTURE METERS, ROOFS. RECONNAISSANCE, SITE SURVEYS.

Nuclear, infrared, capacitance, microwave and impuise radar methods for non-destru tisely detecting moisture in roofs

were evaluated. No system was rehable enough by itself or by cross-checking with another system to eliminate the need for a few core samples of membrane and insulation need for a few core samples of membrane and insulation to verify findings. Airborne infrared surveys are a cost-effective way of reconnoitening numerous roofs at a major installation. However, follow-up on-the-roof surveys are necessary. Of the several grid techniques examined, nuclear surveys were the most reliable. Hand-held infrared surveys are the most accurate on-the-roof method studied. Although an infrared camera costs significantly more than a nuclear meter (\$25K vs \$3K), infrared surveys can be conducted more rapidly. Since the Army has numerous roofs to survey, infrared surveys appear to be the most cost-effective method. For reasons of continuity, accuracy and economy, the Army should establish its own capability to survey roofs for moisture. Implementation should not be at the installation level A centralized team of roof moisture surveying specialists, skilled in poperating infrared equipment but, more importantly, skilled in roofing technology, should be estabspecialists, skilled in operating infrared equipment out, more importantly, skilled in roofing technology, should be established. The team should both conduct and contract for airborne and on-the-roof infrared surveys. The CRRELF-WES/FESA roof moisture research group has initiated development of training aids for use by such a team

RIVER ICE, ICE JAMS, ICE COVER THICKNESS, MEASUREMENT.

MEASUREMENT.

Three shallow stream ice jams which occurred on the Ottauquechee River in Vermont during the 1976-77 winter season
are documented. Measurements of the variation in jam
thickness along the longitudinal profile of the jams are given
along with the variation in surface ice floe sizes. These
measurements are compared with those of previous work
All jams were caused to some extent by hackwater conditions
in the river. The effects of an ice cover and the ice
jams on the longitudinal water surface profiles are examined
and compared with open water conditions

SR 78-04 LARGE MOBILE DRILLING RIGS USED ALONG THE ALASKA PIPELINE.

Sellmann, P.V., et al, Mar. 1978, 23p., ADA-053 536 Mellor, M.

32-3539 PIPELINES, DRILLING, UNITED STATES-ALASKA.

The requirement for installing more than 70,000 vertical support members along elevated sections of the Alaska Pipeline resulted in an extremely large drilling program. Several large drilling units, some specially designed, including rotary (auger), percussive, and combination rotary-percussive units, were selected for this job. This selection of equipment and techniques provided the potential to drill in all conceivable. and techniques provided the potential to drill in all conceivable material types. An examination of these drills in the field, together with product literature, provided some insight into the characteristics of these drills compared with other commercially available drilling units. The pipeline drilling program provided a major impetus for design and development of new equipment in the area of large rotary-percussive and percussive drilling units. The pipeline drills in general showed sound design characteristics in weight, power, thrust, torque, and speed. Many of the auger boring heads could benefit from improvements in shape, angles, cutter position, and in consideration of the center of the hole problem heed for work in this area was indicated by drilling rates, as well as by noticeable improvements in some augers following contractors' field modifications.

SR 78-05 SPECIALIZED PIPELINE EQUIPMENT.

FRESH WATER SUPPLY FOR A VILLAGE SUR-ROUNDED BY SALT WATER-POINT HOPE, ALASKA.

McFadden, T., et al, Apr. 1978, 18p, ADA-054 147, 9 refs.

Collins, C.M.

WATER SUPPLY, GROUND WATER, PERMA-FROST HYDROLOGY.

FROST HYDROLOGY.

Point Hope is a village located on a narrow gravel spit extending eight miles out into the Bering Sea. Studies to locate an adequate fresh water source for the village have yielded two possible supplies which will fill the needs of the village. The first is a ground water supply existing on top of the undulating permafrost layer which underlies the gravel spit. This supply consists of several million gallons of water and can be augmented with snow fences which will drift blowing snow into areas where it will drain into the augmer when it melts. Excess water will overflow the sides of the spit. The second source is a small lake located approximately four miles from the village. The lake provides water of adequate quality and quantity to used as a raw water supply; however, this source is not as desirable since it is surface water and supports a higher level of bacterial contamination. In addition, it is a much greater distance from the village, and longer, much more expensive piping would be required to get the water to the village.

merous refs. passim.

McGaw, R.

FROST ACTION, PAVEMENTS, FROST HEAVE, DRAINAGE, THERMAL CONDUCTIVITY. DRAINAGE, THERMAL CONDUCTIVITY, FROST PENETRATION, SOIL FREEZING, COM-PUTER APPLICATIONS

Before constructing actual pavements with open-graded drain age layers in New Jerses, the influence of the drainage

layer on frost penetration beneath hypothetical pavements was analytically examined. Thermal conductivity values of several New Jersey soils, stabilized drainage layer materials, of several New Jersey soils, stabilized drainage layer materials, and pavement samples were measured using the Guarded Hot Plate method or the probe method frost penetration depths were computed using the modified Berggren equations Mean air freezing indexes used in the computation ranged from 50 deg-days in Atlantic City to 480 deg-days in Newton. Design freezing indexes ranged from 250 deg-days to 900 deg-days for the same two sites Maximum computed frost depths ranged from 0.8 to 2.1 ft beneath conventional pavements, i.e., those without drainage layers for pavements incorporating an open-graded drainage layer, computed maximum frost depths ranged from 0.8 ft to 1.4 ft. It was concluded that frost penetration beneath a pavement including an open-graded drainage layer would be approximately equal to a pavement without the drainage layer at the same site

TUNDRA FIRE AT KOKOLIK RIVER. ALASKA.

MOISTURE METERS, WATER TREATMENT, WASTE DISPOSAL, MODELS.

This report describes the construction, operation and performance of large-scale (90 cm-inside diameter and 150-cm-high) lyameters. These lysimeters can continuously monitor soil moisture flow, soil temperature and redox potential with depth, and sample soil water and soil air with depth. The rate of soil water movement to the groundwater was continuously monitored by a rain gage and a recorder field condition, an automatic sprax system was developed, this system is also described in this report. The total cost of one symmeter is approximately \$650 (1975 estimate) the lysimeters are being used to validate a biophysical-chemical model of wastewater tenovation by application to land. Detailed blueprints of the lysimeters are kept at CRREL, and are available on request. This report describes the construction, operation and perform

SP 78.13 ECOLOGICAL BASELINE INVESTIGATIONS ALONG THE YUKON RIVER-PRUDHOL BAY HAUL ROAD, ALASKA.

Brown, J., ed. Sep. 1978, 131p., ADA-060 255, For this item as a progress report to the U.S. Department of Energy and for individual papers see 32-3888 through 32-3896

RESEARCH PROJECTS, ECOLOGY, ILNDRA VEGETATION, ROADS, CLAY SOILS

Results of the first full year's field research on five projects along the Yukon River-Prudboe flas. Haw Road are reported. Several projects are extensions of investigations begin in 1976 and are being conducted in cooperation with a Ederal

Highway Administration sponsored environmental engineering study. The extent and success of weeds and weedy species along the road and in material sites has been followed for summer 1976 and 1977. In order to document the vegetation along the complex elevational and latitudinal gradient and its potential for impact and recovery, 17 vegetation maps have now been completed, and vegetation Gescribed and plots established at 120 locations along the 600-kilometeriong road. Collections of vascular plants, bryophytes and lichens were made and catalogued for an additional 9 sites. Sampling for soil invertebrates to determine their sensitivity to impact was undertaken at approximately 25 sites.

Sampling for son inverteorates to determine their sensitivity to impact was undertaken at approximately 25 sites. A detailed study of the impact of road dust upon the vegetation was initiated at one tundra site, and four sites were established to monitor the amount of dust transported onto the tundra across 1000-meter-long transects. The clay mineralogy and chemistry of the dust and road material were investigated. SR 78-14

SUBSEA PERMAFROST, SEDIMENTS, SEA WATER, CHEMICAL ANALYSIS, DRILL CORE ANALYSIS, SALINITY.

ANALYSIS, SALINITY.

The analytical data from sediment, interstitial water, and seawater analyses of samples collected near Prudhoe Bay, Alaska, during the period from March to May 1977, are presented Analyses include determinations of moisture, calcium carbonate, and organic carbon contents in the sediment samples and pH, electrical conductivity, alkalinity, and concentrations of sodium, potassium, calcium, magnesium, chloride, and sulfate in the interstitial water and seawater samples. Salinity, ionic balance, and freezing point of the water samples were calculated. The marine sediments in Prudhoe Bay generally contain more calcium carbonate, organic carbon, and interstitial water than the underlying glecula and fluvial gravels. On land, a surficial layer of peat also had high organic carbon and moisture contents. The salimity of the seawater samples varied from concentrated brines near organic carbon and moisture contents. The salmity of the seawater samples varied from concentrated brines near the shore where sea ice is frozen directly to, or is located near, the sea bottom to water which was 1.0 to 1.5 ppt less saline than normal seawater at a distance of approximately 10 to 15 km from shore.

AGE.

This compilation of literature, published in Russian since 1970, comprises 1225 bibliographic citations relating to disturbance and restoration of soils and vegetation. Sixty-five percent of these were found by a manual search of CRREL Bibliography Vols. 25-32, the others were obtained through off-line searches from the relevant computerized data bases and personal files. Only one of these data bases, that of the National Agricultural Library, is shown to be of significance in providing a valuable checking source. The iterature is discussed in chronological feshion, with general statements followed by highlights of each year's contributions. The years 1972 and 1973 produced the most publications, and by 1976 there was a noticeable lag in pickup of publications by the indexing services. A trend is apparent from a reconnaissance and description approach in earlier pears toward are integrated ecosystem approach in more recent publications. Increased consciousness of the effects of disturbance on the permafrost environment, and the importance of restoration and preservation of these environments, are reflected in the recent literature, particularly in symposium proceedings.

SR 78-20 EFFECTS OF WASTEWATER AND SEWAGE SLUDGE ON THE GROWTH AND CHEMICAL

COMPOSITION OF TURFGRASS.
Palazzo, A.J., Nov. 1978, 11p., ADA-061 878, 17 refs.

WASTE DISPOSAL, SEWAGE DISPOSAL, GRASSES, GROWTH, CHEMICAL COMPOSI-

TION.

A greenhouse study was conducted to determine the effects of wastewater and sewage applications on the growth and chemical composition of two turfgrass mixtures. A mixture of tall fescue and annual ryegrass was compared to a mixture of Kentucky bluegrass, red fescue and annual ryegrass. The mixtures were grown in pots of Charlton silt loam in a greenhouse Prior to seeding, soil in some pots was amended with sludge at rates of 45 or 90 g/pot. Commercial fertilizer supplying N. P. and K was incorporated with soil in pots designated as controls. Treated municipal wastewater was applied on unamended and sludge-amended soil at rates of 5 or 10 cm per week. Wastewater and sludge treatment increased yields, and total uptake of N. P. K. Zn. Cd. P. Cu. and Ni by the turfgrasses differed by treatment The two grass mixtures were similar with regard to yields and composition. Larger yields corresponded to greater plant uptake of N. P. K. and metals. SR 78-21

SR 78-21 CLIMATIC SURVEY AT CRREL IN ASSOCIA-TION WITH THE LAND TREATMENT PRO-JECT.

Bilello, M. A., et al., Nov. 1978, 37p., ADA-062 518, 39 tels

Bates, R.E.

MICROCLIMATOLOGY, WASTE DISPOSAL, WATER TREATMENT, WASTE TREATMENT, METEOROLOGICAL DATA.

During 1972, six test cells were constructed at CRRFL for the purpose of studying application of wastewater on various soil types and vegetation. In computeron with this program, a meteroelogical observing station was established in order to obtain basic information on the climate proximate to the test cells. This report describes the equipment and its installation, and provides a duly tabulation equipment and its installation, and provides a duly tabulation of the following observed parameters maximum and minimum air temperatures, relative humidity, dew point, wind speed and direction, precipitation amounts, depth of snow on the ground, solar radiation and pan evaporation. The meteorological data collected during the period starting Oct. 1, 1922, to Mar. 31, 1974, were then summarized, and the results are presented in a series of graphs and line diagrams. The meteorological parameters recorded at CRRF1 were then examined to determine how weather can constrain or

help year-round operation of wastewater application to the land. The positive and negative effects of air temperature, precipitation, wind speed, evaporation and snow cover, with respect to land treatment of wastewater, were evaluated. Although no specific recommendations or conclusions are given, the influences of these climatic elements as observed at the CRREL wastewater site are presented for consideration.

COMPUTER FILE FOR EXISTING LAND AP-PLICATION OF WASTEWATER SYSTEMS: A USER'S GUIDE.

Iskandar, I.K., et al. Nov. 1978, 24p., ADA-062 658.

Robinson, D., Willcockson, W., Keefauver, E. 33-2521

WASTE DISPOSAL, WATER TREATMENT, COMPUTER PROGRAMS.

COMPUTER PROGRAMS.

Two computer programs, both written in BASIC, have been developed to store and retrieve information on enisting wantewater land treatment systems. The purpose of establishing these programs is to provide assistance to design engineers during the planning of new land treatment systems by making available the design criteria and performance characteristics of operating systems. The SFARCH program is designed to locate systems with specific design parameters, such as flow rate, waste type, application rate and mode, ground cover and length of operation. The printout from SEARCH includes a list of articles on similar systems in addition to the design parameters. The UPDATE program is used for the revision of information on file. Currently, there are about 350 domestic and 75 foreign systems on file.

SR 78-21 ENGINEERING ASPECTS OF AN EXPERIMEN-TAL SYSTEM FOR LAND RENOVATION OF SECONDARY EFFLUENT.

Nylund, J.R., et al, Nov. 1978, 26p., ADA-062 923. Larson, R.E., Clapp, C.E., Linden, D.R., Larson, W.E. 33-2522

WASTE DISPOSAL, WATER TREATMENT, WASTE TREATMENT, IRRIGATION, LAND RECLAMATION.

RECLAMATION.

A research system was designed and installed at the Apple Valley Wastewater Treatment Plant, two miles south of Rosemount, Minnesota, to develop agricultural management practices for removal of nitrogen from municipal wastewater effluent. A soil set strigation system was designed and installed to apply wastewater effluent to 12 test blecks, each measuring 60 x 150 ft. A perforated plastic drainage tile was placed lengthwise in each block at a depth oquivalent to the normal water table level and opening at one end of the block into a sampling station. Six blocks were planted to corn and six planted to eight species of forages. The effluent was applied at rates up to 15 ft/yr. This report presents the engineering considerations in the design of a solid act irrigation system and drain the and monitoring system for evaluating the influence of the effluent application and agronomic practices on drainage waters.

ROOF CONSTRUCTION UNDER WINTER-TIME CONDITIONS: A CASE STUDY. Bennett, F.L., Nov. 1978, 34p., ADA-062 519.

ROOFS, COLD WEATHER CONSTRUCTION, INSULATION, CONSTRUCTION MATERIALS.

This report describes construction of the roof of an addition to the Interior City Branch of the First National Book of Anchorage, located in downtown Fairbanks, Alaska, during the 19⁵⁶⁻⁷² winter. The report documents the schoolie and procedure for building the roof, reports successful performance of the roof to date, and presents some general comments on roof construction in the wintertime.

INCREASING THE EFFECTIVENESS OF SOIL COMPACTION AT BELOW-FREEZING TEM-ERATURES.

Haas, W.M., et al, Nov. 1978, 58p., ADA-062 875, 57

Alkire, B.D., Kaderabek, T.J.

SOIL COMPACTION, FROZEN GROUND COM-PRESSION, COMPRESSIVE STRENGTH, SOIL WATER, CHEMICAL REACTIONS.

This report presents data from an experimental program undertaken to determine the effect of low temperatures on the compaction characteristics of a silty sand. The effects of compactive effort and chemical additives were also investiof compactive effort and chemical additives were also investigated to determine possible methods of improving the densities of soils placed and compacted at low temperatures. A single soil type was used throughout the test program, and test results were obtained using Standard and Modified AASHO compactive efforts on an untreated soil prepared and tested at temperatures of 20C and 3C. Additional test series, using the same compactive efforts and temperatures, were performed on the soil after it had been treated with an additive. The amounts of additive used, based on the dity weight of soil, were 3, 2, 1, 0.5, and 0.25% of calcium chloride and 0.5% of soilumn chloride. From the results of the experimental programs, series important concentions concerning the effect of low temperature compaction were drawn. SR 78-26

FIVE-YEAR PERFORMANCE OF CRREL LAND TREATMENT TEST CELLS; WATER QUALITY PLANT YIELDS AND NUTRIENT UPTAKE. Jenkins, T.F., et al, Nov. 1978, 24p., ADA-086 172, 6 refs.

Palazzo, A.J., Schumacher, P.W., Keller, D.B., Gra-ham, J.M., Quarry, S.T., Hare, H.E., Bayer, J.J., Foley, E.S.

34-3449

LAND RECLAMATION, WASTE TREATMENT, WATER TREATMENT, WATER TREATMENT, WASTE DISPOSAL.

The performance of the six land treatment cells is summarized over a five-year period from June 1937 through May 1978. The data presented include quality and volume of wastewater applied and percolate resulting from application of primary and secondary wastewater by spray irrigation. Mass loadings and removals are presented as well as crop production and nutrient uptake. Nutrient bulance sheets are shown which demonstrate the percentage of nitrogen and phosphorus that is attributed to crop uptake and leachate over this period.

SR 78-27

CONSTRUCTION AND PERFORMANCE OF PLATINUM PROBES FOR MEASUREMENT OF REDOX POTENTIAL.

WASTE DISPOSAL, WATER TREATMENT, STA-BILIZATION, PONDS, LININGS, SEALING,

SEEPAGE.

A review of the Interature on wastewater stabilization Iagoon linings, covering the work during the past 20 years, is presented. Design, operating and mointenance experiences are presented for soil scalants, natural scalants, bentonite clays, chemical treatments, gunide, concrete, asphaltic compounds, plastics and elastomers. The characteristics of various materials, applicability to different wastes, construction techniques and details of installation techniques are presented. Installation costs for various materials and comparative costs are summarized. A summary of reported accepage rates for various types of lining materials is presented. A sorvey of the 50 states was conducted to determine the requirements for liners and allowable scepage rates. Requirements are varied and depend upon the local and conditions and the experience of the requisitory agencies with various materials. The trend is toward more stringent requirements. Accepted denays and untallistion procedures are summarized, and detailed denaying of installation techniques are presented. Recommendations of the manufacturers and installers of liners are also presented.

SUMMARY OF CORPS OF ENGINEERS RE-SEARCH ON ROOF MOISTURE DETECTION AND THE THERMAL RESISTANCE OF WET INSULATION.

Tobiasson, W., et al, Dec. 1978, 6p., ADA-063 144, 12

Korbonen C.

33-2525 ROOFS, MOISTURE TRANSFER, DETECTION, INFRARED SPECTROSCOPY.

INFRARED SPECTROSCOPY.

Nuclear, infrared, capacitance, microwave and impulse radar methods for noedistructively detecting meeture in roofs were evaluated. No system was refulled enough by stock or by cross-checking with another system to eliminate the need for a few core samples of membrane and insulation with the send for a few core samples of membrane and insulation of verify findings. Authoric infrared surveys are a confedence way of reconnectering municious roofs at a major insulation.

However, follow-up on-the-oroof surveys are necessary. Of the several grid techniques examined, modern surveys were the most reliable. Hand-held infrared surveys are the most necessary each the-orio furthed studyed. Although necessary. On the severa paragramatical extracts, most in surepsy were the most reliable. Hand-held infrared survers are the most accurate on-the-roof method studend. Although an infrared camera costs significantly more than a market meter (\$27,000 vs.\$3,000), infrared surveys can be conducted more tapelly. Where numerous roofs are to be survered, affrared surveys appear to be the most con-effective method. In-sets measurements have been made of the thermal resultance of well and day portions of roofs. A laboratory appearance has been built to subject 12 in v. 12 in specimens of roof insulation to combined thermal and mostiture gradents. Thermal resultance and mostiture content we periodically determined, and characteristic curves are being developed for various roof insulations.

Runoff from spray application of secondary wastewater efforms on a freested hillside in West Dorrer, Vermont, was monitored for a surveich gerold (11 July)? August 1977). Beth questity and quality of applied efforcit and side drainage were monetored. On-side groundwater and two adjuncts streams were sampled for mater quality. Drainage flows were relatively constant dreing the study, period in spous of Sphyl samble separts to the side. There is evidence that substitutial quartities of water may be leaving the specystic by maxing through the substrate fraginal layer. On a mass basis, 95% of the total integers, 95% of the attitute-integers, 95% of the attitute-integers, 95% of the originic natiogen, 95% of the total phosphorus, and 75% of the BODI were removed by apray application. Heavy precipies mass observed to finish most nativent forms, especially intrincentringers, from the spray size. Groundwater on the spray field contained lower concentrations than did the applied efforms, but higher concentrations than do the applied efforms, but higher concentrations than do the applied efforms, but higher concentrations than those found in total trainage. No hazardous mixtue levels were detected during the study period. However, there was some evidence of microact chierole concentrations in Elia Reads.

ENERGY REQUIREMENTS FOR SMALL FLOW WASTEWATER TREATMENT SYSTEMS. Middlebrooks, E.J., et al, Apr. 1979, \$2p., ADA-070

676, 16 refs. Middlebtooks, C.H.

WASTE DISPOSAL WASTE TREATMENT, PONDS, SEEPAGE, SEEPAGE, COST ANAL

This report summaries energy requerements for small wastewa-ter treatment systems (0.55 - 5 million gallous per day) applicable to military matalations. It compares tansons treatment combinations, and prevents the energy requirements for the most visible alternatives in talking form. It also receives general treatments of the most state of the tennici incriment shirem er y pennicunyet it consensit of nu-trenici incriment shirem er y pennicunyet it consensit of nutenier treatment systems in a formet making it convenient to calculate the energy requirements for many combinations of the components. In addition, it immunitures briefly energy estimates made by others. The report compares typical combinations of unit operations and processes used processes are produce a second quality efficients on the basis of corregions, and concludes that find application systems are the most energy-efficient uniterastic treatment systems and that their are capable of producing an equivalent or higher quality efficient than any other treatment systems.

DESIGN PROCEDURES FOR UNDERGROUND HEAT SINK SYSTEMS.

Stubstad, J.M., et al, Apr. 1979, 186p in var pagns. ADA-CAS 226, 65 refs

Quana, W.F., Grirenberg, M., Best, W.C., Rotros, 33.3427

UNDERGROUND FACILITIES, HEAT TRANS-FER, WASTE DISPOSAL, HEAT RECOVERY, HEAT SINKS This report presents criteria, engineering information and estimation procedures for the disposal of waste heat associated with the generation of power required to supply the needs of hardened defense underground installations. The major emphasis is placed on the temporary disposal of waste heat below ground while the installation is under attack and cannot rely upon aboveground disposal. A series of sample problems is included to illustrate the use of the estimation procedures presented in the report. All of the sample problems are based on the sizing of a heat sink system for an underground nuclear power plant. Under the design criteria which were assumed for the sample problems, it is shown that the combination ice/water type heat sink concepts provide the most cost effective solutions.

SR 79-09 ESTIMATED SNOW, ICE, AND RAIN LOAD PRIOR TO THE COLLAPSE OF THE HART-FORD CIVIC CENTER ARENA ROOF. Redfield, R., et al, Apr. 1979, 32p., ADA-069 323, 19

SEEKING LOW ICE ADHESION.

Sayward, J.M., Apr. 1979, 83p., ADA-071 040, 54 refs 33-4226

33-4220 ICE ADHESION, ADHESIVE STRENGTH, ICE PREVENTION, ICE SOLID INTERFACE, WETTABILITY, COHESION, POLYMERS, ICE REMOVAL, SURFACE PROPERTIES, SURFACE ENERGY.

ENERGY.

Icing impairs operation of helicopters and other aircraft, antennae, power and communication lines, shipping and superstructures, canal locks, etc. Prevention or easier removal of icing requires reduction of its add no strength. Literature study shows that adhesion results from secondary (van der Waais) forces yet exceeds normal cohesive strengths. It depends on free surface energy, low contact angle, good contact and wetting, cleanliness, and texture. Modes of adhesion testing are briefly discussed. Poor adhesion occurs with low energy surfaces or contaminants, e.g. hydrocarbons, fluorocarbons, wares, oils, etc., particularly when textured or porous. The resulting low contact angle, poor wetting and occlusion of air at the interface weaken the bond or provide stress loci which can initiate cracks and failure. Coefficient of expansion differences may help in release fie. Further ideas appear among the 100 abstracts presented. A survey of over 300 manufacturers produced over 100 replies. Half of them offered some 100 products deemed worth testing. These are listed with addresses and contacts. Besides simple resins and other release agents, they include composites which combine low surface energy and stronger materials as micromixture, interpenetrating-network, "plastic-alloy," or filler-matrix systems. About 15 to 20 products appear of special interest. Samples of liquid coating or supplier-prepared panels of many are available for the testing phase to follow.

FREEZING PROBLEMS ASSOCIATED WITH SPRAY IRRIGATION OF WASTEWATER DUR-ING THE WINTER.

Bouzoun, J.R., May 1979, 12p, ADA-070 031, 5 refs.

WASTE TREATMENT, WATER TREATMENT, WASTE DISPOSAL, IRRIGATION, ICE PREVEN-TION.

During the winters of 1975-76, 1976-77 and 1977-78, biologically treated wastewater was applied to land in West Dover,

Vermont. The wastewater was applied using the spray irrigation method at ambient temperatures as low as OF. During the first winter, freezing was a major problem. Modified spray nozzles that were less susceptible to freezing were installed at both the low points and high points of the aboveground spray laterals. During the second and third winters, ice buildup along the spray laterals, particularly in the vicinity of the spray nozzles, caused serious damage to the pipes. Many man-hours were required to cut the ice repeatedly from the laterals. As an experiment to alleviate the problem, several 30- to 36-in risers were installed at an angle of approximately 30 degrees from the vertical on two of the spray laterals during the winter of 1977-78. They functioned well enough to warrant future installation on the entire system of spray laterals.

SR 79-13 PHOTOELASTIC INSTRUMENTATION— PRINCIPLES AND TECHNIQUES. Roberts, A., et al, May 1979, 153p., ADA-072 011, 83 refs. Hawkes, I.

MEASURING INSTRUMENTS, OPTICAL PROP-ERTIES, STRESSES, ELASTIC PROPERTIES, IN-DICATING INSTRUMENTS, PHOTOELASTICI-

TY.

This report contains a detailed review of the theory and design of photoelastic transducers for measuring loads, strains, stresses and pressures. The measurement of engineering parameters under the adverse conditions normally encountered in the mining and civil engineering industries presents great problems, particularly where such measurements are to be made over long periods of time Photoelastic transducers have distinct advantages over competing equipment in this respect in that the parameters to be measured are revealed as light interference fringes, and the measuring gage itself often need consist of nothing ore than simple steel and glass components Examples of such gages are given in the report. The majority of the work reported here was carried out by the staff and students of the Postgraduate School of Mining, Sheffield University.

AL FREEZE THAW.

Road construction activity near Fairbanks, Alaska, in the late fall of 1977, revealed a large exposure of Fairbanks silt containing numerous massive ice features. These exposures are typical of those found in this region. Thaw, during the summer of 1978, caused the upper ice-rich sections to retreat several meters. Geophysical techniques were utilized over these exposures to determine if restauce anomalies of ice wedge dimension could be detected. Magnetic induction measurements at three interioil spacings and low-frequency surface impedance measurements were made about 6 m from the edge of each exposure in April 1978 before thaw commenced. The results agree well with observations of the layering, but most individual anomalies are difficult to interpret because the lateral extent of the ice is unknown

IMPROVED DRAINAGE AND FROST ACTION CRITERIA FOR NEW JERSEY PAVEMENT DESIGN. PHASE 2 (DATA ANALYSIS). Berg, R.L., May 1979, 51p., ADA-071 041, 7 refs. 33-4228

FROST PENETRATION, SUBSURFACE DRAIN-AGE, MOISTURE, FREEZING INDEXES, PAVE-

MENTS.

Before constructing actual highway pavements with opengraded drainage layers, frost penetration depths and moisture
content profiles were measured beneath several pavements
in New Jersey. Air and surface freezing indexes were
measured at three locations during the 1975-1976 and 19761977 winters. All freezing indexes were considerably greater
during the 1976-1977 winter. The modified Berggere equation was used to compute the maximum frost depth at
30 test sites Measured maximum frost depths ranged
from 20.5 in to 52.0 in, while computed maximum values
ranged from 14.0 in to 61.0 in The mean difference
between observed and computed maximum frost penetration
depths was 3.8 in. Maximum frost penetration depths
were computed for hypothetical pavements with open-graded
drainage at four of the test sites It was concluded that
open-graded drainage layers would not significantly change
the frost penetration beneath highway pavements in New
Jersey It was recommended that test pavements be installed
to verify the computations

ROOF MOISTURE SURVEY—U.S. MILITARY

ACADEMY. Korhonen, C., et al, May 1979, 8 refs. Tobiasson, W.

33-4229

ROOFS, WALLS, LEAKAGE, INSULATION, MOISTURE, INFRARED EQUIPMENT, MEASURING INSTRUMENTS.

SURING INSTRUMENTS.

The - "d upper story walls of buildings 745E, 752, and the U.S Military Academy, West Point, New York, surveyed with a hand-held infrared camera to locates. Les of reported wall leaks. An electrical resistance probe was used to determine the relative level of moisture in wall components. Several 3-in-diam core samples of each roof were obtained to verify suspected moisture conditions and to examine the roof membrane in cross section. Wet areas on each roof were outlined with white spray paint. Wall leaks are believed to becaused by wind-driven rain entering the parapet walls in locations where the decorative glaze-coat has spalled off Recommendations for mainternance of these buildings are based on information derived from the infrared survey, electric resistance readings, core samples and visual examinations.

SR 79-17 SMALL-SCALE TESTING OF SOILS FOR FROST ACTION AND WATER MIGRATION. Sayward, J.M., May 1979, 17 p., ADA-071 989, 25 refs.

33-4435 SOIL TESTS, FROST ACTION, SOIL WATER MI-GRATION, FROST HEAVE, ICE NEEDLES.

GRATION, FROST HEAVE, ICE NEEDLES.

A method is described by which frost action (soil heaving and and needle ice) and the use of soil additives for its control can be studied. The apparatus and procedure are simple and convenient, requiring no extensive space or services and using only small quantities of materials. The procedure could be useful in developing a standard test for such purposes where small scale and convenience are requisite. Also described are two simple, small-scale accessory tests that likewise relate to permeability of soils. These evaporation and wetting tests might also have similar use, particularly in the study of water migration-inhibiting additives.

SR 79-18

EVALUATION OF NITRIFICATION INHIBITORS IN COLD REGIONS LAND TREATMENT OF WASTEWATER: PART 1. NITRAPYRIN. Elgawhary, S.M., et al, May 1979, 25p., ADA-071 077, 21 refs.

WASTE TREATMENT, WATER TREATMENT, SOIL MICROBIOLOGY, LAND RECLAMA-TION, ARCTIC REGIONS.

TION, ARCTIC REGIONS.

A senes of laboratory and field tests was conducted to investigate the possibility that nitrapyrin could be useful as a intrification inhibitor in land treatment of wastewater. Laboratory tests included soil incubation and soil column studies. Variables were soil type, temperature, nitrapyrin concentration and method of application to the soil. Experimental designs included two soils, three temperatures (10 and 20C) and three levels of inhibitors in a complete factorial. Forage grasses were present in all treatments, and wastewater containing NH4+ was utilized. Weekly application of wastewater was 5 cm. Soil solution at depth and leachate at 160 cm were collected and analyzed weekly for NH4N and NO3N. That data indicate that nitrapyrin was not effective in inhibiting intrification when applied to the soil surface in soil columns simulating land treatment slow infiltration. The ineffectiveness of the compound under a mode of application where it is mixed and sprayed with wastewater is thought to be due to its volatility, sorption by organic matter, low water solubility and its immobility in soils. Other chemicals such as carbon disulfide and thiocarbonates, which have different characteristics than the intrapyrin, showed promising results. the nitrapyrin, showed promising results Research is under way to obtain conclusive data

SR 79-19 DRAINAGE NETWORK ANALYSIS OF A SU-BARCTIC WATERSHED: CARIBOU-POKER CREEKS RESEARCH WATERSHED, INTERIOR ALASKA

Bredtnauer, S.R., et al. June 1979, 9p. ADA-073 595. 14 refs.

Hoch, D. 34-137

WATERSHEDS, DRAINAGE, SLOPE PRO-CESSES, PERMAFROST.

CESSES, PERMAFROST.

A Strahler stream order analysis and an exterior link length distribution analysis were made of the Caribou-Poker Creeks Research Watershed near Pairbanks, Alaska The drainage network map used for analysis was produced using a 1 2250 scale aerial photograph mosaic Low drainage densities characterize the basins Bifurcation ratios indicate that the overall drainage network is not dominated by strong geologic controls Statistical analysis indicates that bifurcating source links and tributary source links do not belong to the same length population, a characteristic shared by watersheds in other climatic regions of the world Additional analysis indicates that exterior links originating on permafrost

alopes tend to be shorter than those originating on non-permafrost, well-drained slopes.

INFRARED THERMOGRAPHY OF BUILD-INGS: 1977 COAST GUARD SURVEY. Marshall, S.J., June 1979, 40p., ADA-073 596, 9 refs.

BUILDINGS, HEAT LOSS, INFRARED PHO-TOGRAPHY, WINDOWS.

An IRTB (infrared thermography of buildings) field survey, producing 631 thermograms, 127 photographs, and weather data, was conducted during a 14-day study of 10 Coast Guard stations in Maine, New Hampshire and Massachusetts. This report discusses how the survey was initiated and performed with emphasis on details for the benefit of the reader formed with emphasis on details for the benefit of the reader wishing to plan a survey. One hundred twenty selected thermograms and photographs in this report illustrate many types of heat loss and compare thermally ineffective doors and windows with units designated as standards for thermal effectiveness. Radiator heat leakage through walls, mottled moisture patterns on brick walls, infiltration patterns on glass, and poorly covered openings are illustrated. Thermograms of severe heat losses through glass doors, glass transoms, and glass wall panels are also included, and several solutions for individual heat loss problems, such as fiberglass garage doors and porcelain insulated panels, are suggested. Unanticipated survey problems, such as difficulties in obtaining photographs to compare with thermographically discovered artifacts and adjustments to survey techniques for inclement weather, are also discussed. weather, are also discussed.

SR 79-22 **DETERMINATION OF FROST PENETRATION** BY SOIL RESISTIVITY MEASUREMENTS. Atkins, R.T., July 1979, 24p., ADA-071 990. 33-4436

MEASURING INSTRUMENTS, FROST PENE-TRATION, ELECTRICAL RESISTIVITY, FROZ-EN GROUND PHYSICS.

EN GROUND PHYSICS.

Two sensors that depend on changes in soil resistivity were tested. Tests were conducted under a parking area with an asphalt-concrete suil see where salt was periodically applied as part of snow removal operations. For comparison, data were obtained from a resistivity probe, a thermocouple probe and a thermistor probe.

Results indicated that measuring temperature to determine frost penetration can lead to large errors under some conditions, for instance when salt has been applied or when frost is coming out of the ground in spring. The resistivity probe performed reliably during the entire measurement program. It was concluded that resustivity probes have definite advantages which should be has oeen applied or when frost is coming out of the ground in spring. The resistivity probe performed reliably during the entire measurement program. It was concluded that resistivity probes have definite advantages which should be considered when future frost penetration measurement programs are designed.

DOCUMENTATION OF SOIL CHARACTERISTICS AND CLIMATOLOGY DURING FIVE YEARS OF WASTEWATER APPLICATION TO CRREL TEST CELLS.

Iskandar, I.K., et al, July 1979, 82p., ADA-074 712, 14 refs.

Quarry, S.T., Bates, R E , Ingersoll, J 34-743

WASTE DISPOSAL, WATER TREATMENT, SOIL CHEMISTRY, CLIMATOLOGY, METEORO-LOGICAL DATA.

Section 1 deals with physical properties of the two soils used and the changes in soil chemical characteristics. The physical properties of the soil are those most important in controlling the rate of water movement in soils, such as saturated and unsaturated soil hydraulic conductivity, particle size distribution, bulk density, void ratio, available water and specific gravity. The chemical characteristics of the soil that are of potential importance in assessing the short and long-term effects of wastewater application on land include free iron oxides, organic carbon, organic nitrogen, pH, conductivity, cation exchange capacity, exchangeable cations, total and extractable phosphorus, and total and extractable heavy metals. Section 2 summarizes climatic conditions at the CRREL site in Hanover, New Hampshire, and the changes that occurred during the period 1974 to 1978. Climatic parameters include temperature, precipitation, wind speed, and soil temperature at depth. Section I deals with physical properties of the two soils

DETERMINATION OF DISSOLVED NITRO-GEN AND OXYGEN IN WATER BY HEADS-PACE GAS CHROMATOGRAPHY.

Leggett, D.C., July 1979, Sp., ADA-074 411, 25 refs 34-744

LAKE WATER, WATER CHEMISTRY

In this study dissolved oxygen and nitrogen were determined by shaking 20 to 25 ml of water with an equal amount of helium in a 50-ml gas-tight s; ringe and injecting 2 ml of the equilibrated headgas into a gas chromatograph Oxy

gen and nitrogen were separated on a 5-A molecular sieve column at ambient temperature and detected with a hot column at ambient temperature and detected with a hot wire detector, using atmospheric air for calibration. Advantages of this method over previously reported methods are 1) oxygen and nitrogen are determined in a single analysis, 2) no specifically fabricated stripping apparatus is needed, and 3) analysis can be done in the field with completely portable, battery-operated equipment. The method appears to be accurate and reproducible, several lake O2 and N2 profiles were obtained using this technique.

BULLET PENETRATION IN SNOW. Cole, D.M., et al, July 1979, 23p., ADA-074 412, 14 refs.

Farrell, D.R.

SNOW (CONSTRUCTION MATERIAL), PRO-JECTILE PENETRATION, PENETRATION PENETRATION TESTS.

TESTS.

Three types of ammunition, the M193, M80, and M43, were tested. Rounds were fried into snow targets of various thicknesses up to that thickness required to fully stop the projectiles with the three training the training the projectiles. The maximum penetrations for the three rounds tested were 0.70 m. 1 26 m and 1 06 m, respectively. Velocity loss as a function of target thickness was determined by measuring projectile velocity before and after impact of the projectile with the target. The velocity loss vs thickness data showed a sigmoid shape common to the three types of rounds. The impact and early saw angles of the M193 rounds were estimated. Scatter in the test data was attributed, in part, to random variations in the impact yaw angle. The penetration required for a 90 deg yaw was determined by the exit yaw measurements. This was shown to correspond to the inflection point on the velocity loss vs penetration curve. This point is potentially significant in the design of composite fortifications. Discussions deal with basic concepts and definitions, the occurrence and significance of projectile tumbling and the use of laboratory tests for small arms evaluation in show targets. The validity of the methodology used was established by testing M193 rounds in gelatin targets. These results compared favorably with similar test results in literature SR 79-26

SR 79-26 APPLICATION OF HEAT PIPES ON THE TRANS-ALASKA PIPELINE.

Heuer, C.E., July 1979, 27p., ADA-073 597, 26 refs

PIPELINES, HEAT PIPES, HEAT TRANSFER.

PIPELINES, HEAT PIPES, HEAT TRANSFER.

The application of heat pipes on the Trans-Alaska Pipeline is reviewed. The subjects addressed include the general functioning of a heat pipe, the specific heat pipe design used, the different situations where heat pipes were employed, the methods used to develop the heat pipe were employed, the methods used to monitor the operating heat pipes, and the performance of the heat pipes. The discussion is qualitative in nature. Quantitative information is largely omitted to allow coverage of a broad area and because it may be considered proprietary. Nevertheless, the information presented here should give a good appreciation of the quality and complexity of the heat pipe design. The information should also be useful in developing heat pipes for use in other cold regions applications.

EXTENDING THE USEFUL LIFE OF DYE-2 TO 1986, PART 1: PRELIMINARY FINDINGS AND RECOMMENDATIONS.

Tobiasson, W., et al, July 1979, 15p., ADA-074 733, 3 refs.

Korhonen, C, Redfield, R.

COLD WEATHER CONSTRUCTION. SHEETS, STEEL STRUCTURES, STRESSES.

SHEETS, STEEL STRUCTURES, STRESSES.

DEW Line Ice Cap Station DYE-2 appears to need major work within the next few years to extend its useful life to 1986. The structural steel frame is overstressed in a few areas, and the lower portion of the subsurface timber russ enclosure is in bad condition. Additional performance measurements are needed during 1979 to determine the rate of secondary stress in the structural steel frame and the rate of deterioration of the truss enclosure. With this information, a decision can be made whether to move the building sideways onto a new undistorted foundation or to stabilize it in-place by encapsulating the lower 52 ft of the substructure in ice.

UTILIZATION OF SEWAGE SLUDGE FOR TER-RAIN STABILIZATION IN COLD REGIONS.

Gaskin, D.A., et al, Aug. 1979, 36p, ADA-074 725. 10 refs For Part 1 see 32-1368

Palazzo, A.J., Rindge, S.D., Bates, R.E., Stanley, L E 34-746

SLUDGES, SEWAGE DISPOSAL, SOIL STABILI-ZATION, VEGETATION

From June 1975 to Sep 1976, a research/demonstration study was conducted at CRRLL in Hanover, New Hampshire, to investigate the use of sewage sludge, commercial fertilizer and cultivation techniques for terrain stabilization in cold regions. Twenty-seven test plots on a 16-deg west-facing slope received various combinations of 1) surface preparation village. (tilling, buildozer tracking, or compacting), 2) nutrient source (sewage sludge or fertilizer), 3) mulching agent (wood fiber

mulch or peat moss), and 4) tacking agent (Terra Tack III or Curasol) The plots were seeded in either the spring or fall with a constant seed mixture. The effectiveness of the treatments was determined through vegetation yields and soil loss measurements

MASS WATER BALANCE DURING SPRAY IR-RIGATION WITH WASTEWATER AT DEER CREEK LAKE LAND TREATMENT SITE. Abele, G., et al, Aug. 1979, 43p., ADA-080 649, 3 refs.

McKim, H.L., Brockett, B.E.

WATER TREATMENT, WASTE TREATMENT, WATER BALANCE, SEWAGE TREATMENT, IR-RIGATION.

RIGATION.

The water budget for a 36-ha test area was calculated during and two days after a 27-cm (equivalent to 991,000 l) application of wastewater. By computing the water remaining in the soil from soil sample water content data, calculating the amount lost to evapotranspiration and measuring the underdrain flow rate, it was possible to calculate the water budget to within 95% of the actual amount applied. The accuracy in computing the soil water content is critical in this case, a 1% variation of error in the volumetric water content is equivalent to nearly one third of the total water applied. water applied.

BACTERIAL AEROSOLS FROM A FIELD SOURCE DURING MULTIPLE-SPRINKLER IR-RIGATION: DEER CREEK LAKE STATE PARK,

Bausum, H T, et al. Sep 1979, 64p., ADA-077 632, 18

Bates, R.E., McKim, H L., Schumscher, P W., Brockett, B E., Schaub, S.A.

WATER TREATMENT, WASTE DISPOSAL, IRRIGATION, AEROSOLS, MICROBIOLOGY

An evaluation of microbiological aerosols resulting from the spray irrigation of wastewater under known atmospheric stability conditions was performed during July and August 1978 at the Deer Creek Lake land treatment system in Ohio In the experiment, ponded chlorinated wastewater was sprayed In the experiment, ponded chlorinated wastewater was sprayed onto a 6-acre test area with 96 impact sprinklers representing a multi-votree field aerosol distribution system. Approximately 99.9% of the wastewater applied to the 23-hectare test area fell within the area of influence of the sprinkler (about a 20-m diam circle around the sprinkler river) with only 0.10% of the applied wastewater aerosolized. Indigenous total aerosols bacteria in the wastewater and resultant aerosols were sampled and analyzed. Fluorescent dye studies were also performed to characterize the aerosol cloud without the effects of biological decay. During all of the aerosol tests continuous on-site meteorological measurements were made and wastewater chemical parameters monitored. SR 79-33

TEST OF SNOW FORTIFICATIONS.

Farrell, D.R., Oct. 1979, 15p., ADA-078 742, 16 refs.

PENETRATION TESTS, MILITARY ENGINEER-ING, SNOW (CONSTRUCTION MATERIAL), FORTIFICATIONS, SMALL ARMS AMMUNI-

A field study was conducted to 1) more accurately define the degree of protection offered by simple snow fortification and 2) evaluate the effort required by infantry troops to build such fortifications when only basic tools are available. A seven-man infantry squad, equipped with standard issue snow shovels and an arctic sled (Akhio), constructed several snow shovels and an arctic sled (Aknio), constructed several simple snow structures. Construction was made more difficult by the imposition of a camouflage discipline requirement. When completed, three positions were subjected to M16A1 file fire while the infantry squad executed a simulated tactical assault. A fourth and much larger position was tested with simulated covering fire from a M2HB 50-caliber machine gun. None of the 556-mm bullets fired by the squad from ranges of 200 m to as close as 10 m managed to penetrate the 1.8-m-thick snow embankments. The 127-mm-diameter bullets fired from the M2HB at a range of 250 m were all stopped by 3.0 m of packed snow. The camouflage considerations and the shallow snow conditions increased the construction time for the three small emplacements by almost a factor of four, and for the larger emplacement by almost a factor of three. But the squad still handled a volume of packed snow that was equal to 37 times the volume of unfrozen soil conditions the advantages of using snow would be significantly greater. simple snow structures Construction was made more difwould be significantly greater.

POST OCCUPANCY EVALUATION OF A PLANNED COMMUNITY IN ARCTIC CANADA. Bechtel, R.B. et al, Feb. 1980, 27p., ADA-082 162, 4

refs. Ledbetter, C B.

35-2596 URBAN PLANNING, HOUSES, SITE SURVEYS, BUILDINGS, ECOLOGY

This report describes a post-occupancy evaluation of a small mining community in the high Arctic Providing superior housing, having wives work and integrating singles, limits (the indigenous people) and families successfully established a viable community. Lewer problems were encountered than is usual in other isolated cold regions communities.

The central focal point of the town, a large dome, was diluted by later construction of buildings housing separate recreational and social facilities.

Since the buildings are too costly to remove, the only method of restoring the focal point is to build connecting links at upper levels of the recreational buildings.

SOME ASPECTS OF SOVIET TRENCHING MA-CHINES

Mellor, M., Feb. 1980, 13p., ADA-082 176, 1 ref. 35-2597

TRENCHING, FROZEN GROUND, EARTH-WORK, EQUIPMENT, DESIGN.

WORK, EQUIPMENT, DESIGN.

Technical characteristics of Soviet trenching machines are assessed and compared with those of similar machines built in the United States and Europe. The report deals with transverse rotation machines and belt machines, considering rotor speeds and belt speeds, tool speeds, power/weight ratios, power density, traverse speeds, and effective mean cutting pressures. The probable capabilities of Soviet machines for cutting frozen ground are assessed. It is concluded that, while general design characteristics are satisfactory, construction and product development are weak, and performance in frozen ground is not expected to be impressive

DOCUMENTATION FOR A TWO-LEVEL DY-NAMIC THERMODYNAMIC SEA ICE MODEL. Hibler, W.D., III, Feb. 1980, 35p., ADA-084 273, 9 refs.

34-3329

SEA ICE, ICE THERMAL PROPERTIES, THER-MODYNAMIC PROPERTIES, HEAT TRANS-FER, ICE MECHANICS, ICE COVER THICK-NESS, MATHEMATICAL MODELS, COMPUTER PROGRAMS, RHEOLOGY.

A discussion of the numerics and computer code for a two-level dynamic thermodynamic sea ice model is presented. For interested users a listing of the computer code and results from a 21-day test run are included as appendices. results from a 21-day test run are included as appendices, To a large degree this report is meant to serve as an extended appendix to an article by the author in the Journal of Physical Oceanography (see 34-741) describing his model and a variety of simulation results. The model consists of a two-level ice thickness distribution coupled to the ice dynamics by a plastic rheology. In addition to the ice interaction, the momentum balance includes nonlinear wind interaction, the momentum balance includes nonlinear wind and water drag terms, Corolis force, and inertial and momentum advection terms. The numerical scheme is formulated in an energy-conserving manner in a fixed Eulerian gnd which allows simulation over unlimited time intervals. The momentum balance (including inertial terms) is numerically treated in a semi-implicit manner so that time steps of up to one day in length may be used if desired. The boundaries, grid size and time step magnitude are easily modified so that the model should have application to a variety of climate and forecasting problems

SR 80-09

THICKNESS-TENSILE STRESS RELA-TIONSHIP FOR LOAD-BEARING ICE Johnson, PR, Feb. 1980, 11p., ADA-084 274, 3 refs. 34-3330

ICE COVER STRENGTH, ICE LOADS, ICE CROSSINGS, ICE ROADS, TENSILE PROPERTIES, STRESSES, ICE COVER THICKNESS

The "bearing capacity" of a floating ice sheet is of considerable interest. The pattern of ice thickness vs tensile stress for a fixed load and fixed ice properties was examined and showed some constant relationships. It proved possible to completely describe the ice thickness-tensile stress pattern in terms of a single number.

When the load was changed by the constant the geometry the geometry. to completely describe the ice thickness-tensine sites patient in terms of a single number. When the load was changed by increasing the payload but not altering the geometry of the load pattern, other relationships were found that described the lensile stress in the ice sheet for any combination of payload and ice thickness. This provides a simple method of finding tensile stress in the ice that can be used in the field. Further studies are planned.

OPERATION OF THE CRREL PROTOTYPE AIR TRANSPORTABLE SHELTER.
Flanders, S.N., Feb. 1980, 73p., ADA-084 275.

PORTABLE SHELTERS, COLD WEATHER PER-FORMANCE, TRAPLANES, LOGISTICS TRANSPORTATION

This report describes the operation of the CRREL prototype This report describes the operation of the CRREL prototype air-transportable shelter which was designed specifically for use in cold regions. The operating instructions cover moving the shelter on its own wheels or skis, loading it onto a truck or milit, by transport aircraft, slinging it from a helicopter or preparing it is shipment as an ISO container. The report details how to such this shelter and expand it to about double its transport size. The report also covers operation of the utility systems, including the on-board alternator set, the primary and auxiliary heating systems, the water system, and various safety systems.

SR 80-11 SNOW FORTIFICATIONS AS PROTECTION AGAINST SHAPED CHARGE ANTITANK PRO-

Farrell, D.R., Mar. 1980, 19p, ADA-084 276.

34-3322 SNOW STRENGTH, FORTIFICATIONS, COLD WEATHER CONSTRUCTION, COLD WEATHER OPERATION, SNOW (CONSTRUCTION MATERIAL), EXPLOSION EFFECTS, IMPACT TESTS, DETONATION WAVES, EMBANK-MENTS.

MENTS.

This report chronicles an investigation of the effectiveness of snow fortifications. The test was planned to observe and measure how packed snow absorbs the energy of high explosive antitiank (HEAT) ammunition. In the test plan both the possibility of non-detonation due to insufficient resistance in snow and the rate of deterioration of a snow embankment with repeated impacts were considered. The 90-mm M67 recoilless rifle was used because it has a relatively low velecity, and its charge was more likely to not detonate that snow can be used to good advantage for building expedient fortifications, particularly in situations where large volumes of snow have to be cleared from roads and airfields

DRILLING AND CORING OF FROZEN GROUND IN NORTHERN ALASKA, SPRING

Lawson, D.E., et al, Mar. 1980, 14p., ADA-084 277. 6 refs.

EXTENDING THE USEFUL LIFE OF DYE-2 TO 1986. PART 2: 1979 FINDINGS AND FINAL RECOMMENDATIONS.

Tobiasson, W, et al, Apr. 1980, 37p., ADA-084 278,

Tilton, P.

RADAR, STATIONS, SNOW ACCUMULATION, ICE FORMATION, SNOW STRENGTH, LOADS (FORCES), STEEL STRUCTURES, STRESSES, COST ANALYSIS.

COST ANALYSIS.

A major construction effort is needed at Dew Line Ice Cap Station DYE-2 to extend its useful life to 1986. That work should be done as soon as possible because the trius enclosure is deteriorating rapidly. Although a 210-ft sideways move as was accomplished at DYE-3 in 1977 is technically feasible, the alternative of backfilling the truss enclosure with ice is expected to cost about \$2.7 million less. Unless there is a strong possibility that DYE-2 will be needed for many years beyond 1986, the ice backfill alternative is recommended.

CRREL ROOF MOISTURE SURVEY, PEASE AFB BUILDINGS 35, 63, 93, 112, 113, 120 AND

LATION, MEASURING INSTRUMENTS
We surveyed the roofs of seven buildings at Pease AFB
with a hand-held infrared scanner to detect wet insulation.
We used white spray paint to outline the wet areas and
took core samples of the built-up membrane and insulation
to verify our findings. Flashing defects around penetrations
and bordering walls appear to be the major cause of the
wet insulation found on these roofs. Since most problem
areas are localized, we directed expansive most problem
toward salvaging as much of each roof as is economically
possible.

NITROGEN TRANSFORMATIONS IN A SIMULATED OVERLAND FLOW WASTEWATER TREATMENT SYSTEM.

Chen, R.L., et al, Apr 1980, 33p., ADA-084 280, 36

Patrick, W.H, Jr. 34-3365

WASTE TREATMENT, WATER TREATMENT, NUTRIENT CYCLE, SOIL CHEMISTRY.

NUTRIENT CYCLE, SOIL CHEMISTRY.

Treating wastewater in properly designed and operated overland flow systems results in significant amounts of N being removed through nitrification-denitrification reactions. Application of wastewater containing NH4-N in a simulated overland flow model led to the disappearance of ammonium and the formation of nitrate in oxidized surface soil. The N balance in the simulated overland flow system was estimated by using labeled 15 N. The amount of N removed in the system depends upon dentitrification rates of this study indicated that N adsorption on the soil complex and uptake of applied ammonium by vegetation accounted for the N removed in the overland flow systems. The adsorbed ammonium on the acrated surface soil mass was attiffied and converted to oxidized forms of N. The intrate thus formed diffused downward to the reduced zone during subsequent wastewater applications. Some of this nitrate thus formed diffused downward to the reduced zone during subsequent wastewater applications. Some of this nitrate then denitrified and converted to gaseous form of N or was assimilated and reduced by plant life. Results of the overland flow studies indicated that approximately 55-68% of wastewater NH4-N added to the simulated overland flow system was unaccounted for in controlled laboratory environments. This NH4-N was presumably returned to the atmosphere

INFLUENCE OF NOSE SHAPE AND L/D RATIO ON PROJECTILE PENETRATION IN FROZEN SOIL.

Richmond, P.W., Apr 1980, 21p., ADA-085 398, 10 refs.

FROZEN GROUND, PROJECTILE PENETRA-TION, SOLUTIONS, EXPERIMENTATION

TION. SOLUTIONS, EXPERIMENTATION
This report presents the results of a laboratory test program designed to determine the applicability of two analytical solutions to projectile penetrations in fiozen soils. The test program consisted of firing small caliber cylindrical projectiles into frozen soil targets. Four types of 7.9-min-diam projectiles were tested. Two with a hemispherical nose the other two flat-nosed, with both long flength/diameter + 4) and short (L/D=2) versions of each nose shape to determine the control of the versus impact velocity data are presented. Comparisons of the data indicate that a flat-nosed projectile is a less efficient penetrator than one of equal weight with a hemispherical nose. A small increase in resistance to penetration is observed for an increased I. D. ratio.

DEICING A SATELLITE COMMUNICATION ANTENNA.

SEDIMENT TRANSPORT, BOTTOM SEDI-MENT, ICE SCORING, ICE EROSION, BANKS (WATERWAYS), RIVER ICE, HYDROLOGY.

(WAIEKWAYS), RIVER ICE, HYDROLOGY.

A three-year study of sediment displacement was conducted on a short section of the Ottauquechee River in Vermont that has erosional problems caused by ice. The results of cross-sectional surveys showed large quantities of the bank eroded and deposition in the bed within the study area. The erosion appears to have been caused by 1) the ice seouring the banks and 2) ice plugging the channel and diverting the flow toward the banks.

DYNAMICS OF NH4 AND NO3 IN CROPPED SOILS IRRIGATED WITH WASTEWATER. Iskandar, I K, et al, June 1980, 20p, ADA-090 575,

Parker, L.V., McDade, C., Atkinson, J., Edwards, A.P.

WASTE DISPOSAL WATER TREATMENT, IR-RIGATION, SOIL CHEMISTRY, NUTRIENT CY-CLE, AGRICULTURE

CLE, AGRICULTURE

The objectives of this field study were 1) to obtain information on the dynamic behavior of wastewater NH4 and NO3 in soils, 2) to determine the relative abundance of NH4 and NO3 in soils receiving wastewater, and 3) to evaluate the seasonal effect on the fate of wastewater NH4 applied to soils in a slow infiltration system. The study was conducted using an on-going test plot which contained two soil types and was covered with forage grass. Samples were collected in June and October to study the seasonal effect on the dynamic of N. The concentrations of NH4 and NO3 in the soil reached a daily, quasi-steady state condition. The seasonal effect on the relative amounts of NH4 and NO3 was similar but there was always more NH4 than NO3. The concentrations of both NH4 and NO3 in soil profile were high at the surface and decreased with depth, consistent with the higher CEC, the slow movement of NH4 in soils, and the higher organic matter content in the surface. Both NH4 and NO3 concentrations were higher in the finer texture Charlton silt loam soil than in in the surface Both NH4 and NO3 concentrations were higher in the finer texture Charlton silt loam soil than in the coarser texture Windsor sandy loam soil

ICE ADHESION TESTS ON COATINGS SUB-JECTED TO RAIN EROSION. Minsk, L.D., July 1980, 14p. ADA-089 698.

ICE ADHESION, ICE PREVENTION, PROTECTIVE COATINGS, HELICOPTERS, TESTS

TIVE COATINGS, HELICOPTERS, TESTS
Screening tests to select keephobic constings displaying low
tee release forces, both before and after exposure to rain
erosion in a whirling arm simulator, were performed on
approximately 60 commercial materials. A unique linear
ball-slide shear test apparatus was designed to provide pure
shear forces. No coating survived the erosion test to
give an interfacial shear strength as low as 15 psi (103
kPa), an arbitrarily established goal
showed shear strengths between 30 and 45 psi (20° and
310 kPa) after rain crosson.

DYNAMIC TESTING OF FREE FIELD STRESS GAGES IN FROZEN SOIL.

Aitken, G.W., et al, July 1980, 26p., ADA-089 676, 6

Albert, D.G., Richmond, P.W. 35-2601

FROZEN GROUND MECHANICS, STRESSES, IMPACT TESTS, SHOCK WAVES, SOIL ME-CHANICS, WAVE PROPAGATION.

CHARICS, WAVE PROPAGATION.

This report describes an attempt to develop a procedure for dynamic calibration of free-field soil stress gages embedded in a soil sample. The method presented utilizes a dropative impact testing machine and a small, instrumented container of soil. The velocity history of a shock pulse applied to the soil sample is measured and the applied stress computed, this value is then compared with data obtained from stress gages embedded in the soil. The results showed that the procedure is adequate for unfrozen soil, but for frozen soil the accuracy in the measurement of compressional wave velocity needs to be increased to obtain useful results

REVIEW OF TECHNIQUES FOR MEASURING SOIL MOISTURE IN SITU.

Walsh, J.E., Arion, D.N.

SOIL WATER, ELECTROMAGNETIC PROPERTIES, TENSILE PROPERTIES, CLIMATIC FAC-

Recently there has been an increased interest in the in-situ measurement of soil moisture content in the areas of situ measurement of soil moisture content in the areas of hydrology, meteorology, agriculture and environmental studies. Current methods generally have limitations, depending upon the use of the data, that greatly influence acquisition and reliability of the soil moisture determination. This report discusses gravimetric nuclear, electromagnetic, tensiometric, and hygroscopic techniques and the advantages and disadvantages of using the techniques. Emphasis is placed on the tensiometric and electromagnetic techniques. These two measurements when coupled would supply information on the wetting and drying soil moisture characteristic curves and thereby provide a means of tracing moisture movement under field conditions in cold climates.

Berg, R.L 35-977

SOIL FREEZING, FROST PENETRATION, SOIL STABILIZATION, SOIL WATER, FROST RESIST-ANCE, PAVEMENTS, ADMIXTURES, LIMING, DESIGN

This report describes the construction, instrumentation, and performance of membrane encapsulated soil layer (MESL) pavement test sections at the U.S. Army Cold Regions Research and Engineering Laboratory in Hanover, New Hampshire, from 1973 to 1978. Membrane encapsulated soil layer and Engineering Laboratory in Hanover, New Hampshire, from 1973 to 1978 Membrane encapsulated soil layer construction involves using a waterproof membrane to protect low grade soils from absorbing moisture, especially during the freezing process Most of these lower grade soils are frost-susceptible; in these soils water can be drawn to the freezing zone to form toe lenses, which in turn cause heaving of the surface. Lime, flyash, and sodium chloride were added to a silt material prior to encapsulation. These additives were incorporated to add strength to the silt, absorb excess moisture, and increase its load-supporting capabilities Results show that 1) the moisture content within the MESL sections remained relatively constant over the five years of testing, 2) a nonencapsulated lime-flyash-stabilized silt material heaved 8 8 times as much as the identical material which was encapsulated, 3) the lime-flyash-stabilized MESL, had twice the strength of the plain or salt-stabilized MESL, 4) the silt with the additives had less frost heave within the MESL than the untreated silt. In summary, MESL's can be constructed to perform well in cold regions, thereby replacing high quality aggregates which are being depleted.

DESIGN AND CONSTRUCTION OF FOUNDA-TIONS IN AREAS OF DEEP SEASONAL FROST AND PERMAPROST.

OVERLAND FLOW: REMOVAL OF TOXIC VOLATILE ORGANICS

Jenkins, TF, et al, Feb. 1981, 16p., ADA-097 576, 34

Leggett, DC, Martel, C.J, Hare, HE

35-2581 WASTE TREATMENT, WATER TREATMENT, FLOODING, LAND RECLAMATION, WATER CHEMISTRY.

A small-scale overland flow system was studied to determine its effectiveness in reducing the levels of volatile trace organics in municipal wastewater. Chlorinated primary wastewater, water collected from the surface at various points downslope, water collected from the surface at various points downslope, and runoff were analyzed by gas chromatography/mass spectrometry using a purge and trap sampler. The results indicated that overland flow was effective in reducing the levels of these substances by 80-100% depending on the specific substance and the application rate. The removal mechanism was found to follow first order kinetius. The most likely mechanism to explain the observed behavior is volatifization. Comparison of the experimental results with theoretical prediction using published models resulted in reasonable agreement considering the complexity of the system compared to the model systems.

PLANT GROWTH ON A GRAVEL SOIL: GREEN-HOUSE STUDIES.
Palazzo, A.J., et al, Mar. 1981, 8p., ADA-098 598, 9

Graham, J.M. 35-3692

GRASSES, GROWTH, SOIL STABILIZATION, GRAVEL NUTRIENT CYCLE

GRAVEL NUTRIENT CYCLE.

Two greenhouse studies were performed with gravel soils to determine the requirements for mitrogen (N), phosphorus (P), and potassium (K) for grave establishment and to assess the establishment performance of 18 types of graves. The fertilizer study consisted of 40 treatments, each representing a different combination of apphiation rates of N, P, and K. A seed mixture containing "Sugget Kenticks bluegrass" (Pennlaw), ted fescue, and annual regrass was sown, and the plants were harvested 133 days after sowing. Plant teal and root weights were measured, and soil samples were analyzed for pH, P. K and soluble saits. In the grass study, 15 grasses were grown for 76 days. All treatments

were fertilized at the beginning of the study. Plant establishment was periodically assessed and yields were measured at the end of the study. In the fertilizer study, N and P were shown to be limiting to leaf growth on this soil Applications of P were the most beneficial for root growth Needs for K were less evident, but it was required for maximum leaf growth at the higher application rates of N and P. The greatest yields were recorded when all three elements were applied, while at the lower application rates only N and P were required to promote growth.

UPPER OCEAN TEMPERATURE, SALINITY AND DENSITY IN THE VICINITY OF ARCTIC DRIFT STATION FRAM 1, MARCH TO MAY 1979

ICF JAMS, FLOOD CONTROL, ICF CONDI-TIONS

On City, Pennysivania, is at the confluence of Oil Creek and the Aliegheny River—The basiness district fies within the flood plain of Oil Creek, and as of the winter of 1930, 25 ite jam flooding events had occurred since the mid.

1800's. An investigation was done to determine why Oil City was subject to perennal ice jam fande blemial ice jam floods. Ice conditions were analyzed and it was determined how and why the jams occurred. By controlling where the initial ice cover forms, Oil City's ice jam floods can be alleviated. Ice control structures will be used to encourage the early formation of ice cover and hence climinate frazil ice. This will greatly reduce the amount of ice which currently develops in both Oil Creek and the Allegheny River.

LIMNOLOGY, LACUSTRINE DEPOSITS, CHEMICAL COMPOSITION, BOTTOM SEDI-MENT.

This study characterizes the sediments from Lake Koocanusa this study characterizes the sequents from Lake Koocanusa (Libby Dam reservoir). Montana, in terms of their ability to sorb and release P. Sediment samples were collected at 12 stations located between the U.S.-Canadian border and Libby Dam (42 miles downstream of the border) during July 1977. The sediments from Lake Koocanusa are raleared. July 1977. The sediments from Lake Koocanusa are ralcareous, low in organic matter (< 2.3%), and have a sity loam or loam texture. Most of the P associated with these sediments was in the inorganic form (> 85%), which was highly correlated (r=0 89) with oxalate extractable Fe in the sediment. Sorption tests, with concentrations of either I or 10 mg P/g sediments, showed that these sediments have limited ability to sorb additional P from concentrate solutions. The maximum amount sorbed at the lower P concentrations was 67% of the added P and was highly correlated with oxalate extractable Fe in the sediments. Desorption studies showed that very small amounts of both the originally bound P (1 to 2%) and the added P (< 6.3%) were released. Koocanusa act as a P sink.

PROCEEDINGS OF THE INTERNATIONAL SO-CIETY FOR TERRAIN-VEHICLE SYSTEMS WORKSHOP ON SNOW TRACTION MECHAN-

ICS, ALTA, UTAH, JAN. 29-FEB. 2, 1979. Harrison, W.L., ed, July 1981, 71p., ADA-106 972, Refs. passim. For individual papers see 36-1391 through 36-1397. 36-1390

SNOW MECHANICS, SNOW COMPRESSION, TRACTION, TRAFFICABILITY, VEHICLE WHEELS, TRACKED VEHICLES, MEETINGS. MATHEMATICAL MODELS.

This report reviews the state of the art of snow traction mechanics and presents the results of a limited field exercise that allowed participants to observe and practice current snow measurement processes and vehicle test procedures. The prime recommendations of the workshop attendees were 1) the use of parameters basic to the laws of physics for the classification of snow strength, and 2) the use of instrumented tracked and wheeled vehicles for snow strength measurements.

CD \$61.17

SR 81-17 MACROSCOPIC VIEW OF SNOW DEFORMA-TION UNDER A VEHICLE.

Richmond, PW., et al, July 1981, 20p., ADA-107 038, 10 refs.

Blaisdell, G.L.

SNOW DEFORMATION, SNOW COMPRESSION, LOADS (FORCES), VEHICLES, SNOW DENSITY, STRESSES, SNOW COMPACTION, TESTS.

TESTS. In this report the deformation of snow under a vehicle is discussed. For snow with an initial density of less than 0.45 Mg cu m, load transfer through shallow snow is shown to be attenuated by an interfacial boundary force. Evidence is presented that shows the existence of a density distribution in the deformed area. Results of a laboratory plate-sinkage test on sintered snow support this analysis Maximum values obtained for the interfacial boundary force range from 1355 to 2670. S when the average density of the deformed area is about 0.5 Mg/cu m.

BOTTOM HEAT TRANSFER TO WATER BO-DIES IN WINTER.

O'Neill, K., et al, Sep. 1981, 8p., ADA-106-977. Ashton, G.D.

WATER TEMPERATURE, FREEZING POINTS, HEAT FLUX, HEAT TRANSFER. BOTTOM SEDIMENT, LIMNOLOGY, LAKES, PONDS, WINTER.

In many surface water bodies, water temperature closely follows ambient air temperature. This means that warmer water in winter absorbs heat from below. The extent and pattern of winter heat gain is constrained by the fact that the water temperature does not fall below the freezing point. On the basis of a few simple assumptions, governing equations are solved here pertaining to heat flow in bottom sediments. The results are presented in general nondimensionalized curves. These allow estimation of water/sediment heat flure for each waterships. sionalized curves. These allow estimation of water/sediment heat flux for any particular case, given truncation of the water temperature curve at the freezing point. The user must supply pertunent yearly air temperature mean and amplitude of variation, together with the thermal diffusivity for the bottom material. The governing equations are solved using a higher order finite element method which solves directly for temperature gradients and hence for heat flux. Thus the method provides particularly accurate flux values at high efficiency. The results illustrate in detail how winter water heat gain is less in cases where mean air temperatures are lower.

SR 81-19 MIZEX—A PROGRAM FOR MESOSCALE AIR-ICE-OCEAN INTERACTION; EXPERIMENTS IN ARCTIC MARGINAL ICE ZONES. 1. RE-SEARCH STRATEGY.

This document describes the research strategy for a series of mesoscale studies of arctic marginal ice zones. The main goal of this program is to gain a better understanding of the processes occurring at the ice margin. These processes are relevant to climate, weather forecasting, petroleum exploration and production, marine transportation, naval operations, and commercial fisheries. In addition MIZEX will aid in determining what modifications to existing tee-ocean-atmospheric models are needed for better prediction near the

SR 81-20 MINE/COUNTERMINE PROBLEMS DURING WINTER WARFARE. FINAL REPORT OF A WORKSHOP.

Lunardini, V.J., ed, Sep. 1981, 43p., ADA-107 047.

EXPLOSIVES, COLD WEATHER PERFORM-ANCE, SNOW COVER EFFECT, BLASTING, FROZEN GROUND, RESEARCH PROJECTS.

FROZEN GROUND, RESEARCH PROJECTS.

The possibility of modern warfare being waged under cold weather condutions has raised questions about the effectiveness of conventional and new mine systems during the winter A workshop on mine/countermine winter warfare was held at the U.S. Army Cold Regions Research and Engineering Laboratory, 21-23 October 1980, to define problems related to cold climates. The designer, developer and user communities sent 22 representatives from 16 organizations outside of CRREL. I scussion papers were prepared by four groups, covering emplacement of mines, mine performance, detection of mines, and neutralization of mines is was on the unique problems of the whater environment. It appears that the U.S. has the capability to conduct defensive warfare during the summer but is not adequately prepared for mine/countermine winter warfare. Test and research programs are called for to compensate for the prior lack of consideration of the winter environment, to adequately winterize new mine/countermine systems, and to formulate appropriate doctrine for defensive winter warfare.

BOTTOM SURFACE, FRAZIL ICE, ICE JAMS, PERMAFROST, OIL SPILLS.

In 1974 personnel at the US Army Cold Regions Research and Engineering Laboratory (CRREL) began using an impulse radar system to profile accumulations of ice forms. Through field experience the system has been modified so that it can be effectively used as a profiling system, in a ground or airborne configuration, in certain high-noise environments. The system can penetrate fresh water and media with a high water content. For instance, frazil and brash ice accumulations with approximately 50% water have been profiled to a depth of 25 to 35 ft. As a result of the CRREL modifications, the system has found extensive and vaned applications as a low-level remote sensing tool. Applications include profiling ice accumulations (including ice jams), river beds, sheet ice, permafrost, subsurface ice masses, river bank revetements through air-entrained water, snow covers, sea ice, icebergs, and peat bogs. Limited laboratory work has also shown that the impulse radar system may be able to detect oil and gas under sa ice. Selected applications and data are presented used mainly for research, the CRREL system needs further development to make it useful to operational units. Additional development of hardware and software is recommended.

SITE INVESTIGATIONS AND SUBMARINE SOIL MECHANICS IN POLAR REGIONS. Chamberlain, E.J., Oct. 1981, 18p., ADA-108 269, 44

refs 36-1644

CHONS, BEAUFORT SEA.

Placing oil exploration and production structures offshore in the Alaskan Beaufort Sea will require careful site investigation and evaluation of submanne soil mechanics. Ice-bounded permafrost occurs widely under the Beaufort Sea floor. Its engineering properties are important to the design of offshore structures. If they overconsolidated clays also occur widely and interfere with access to gravels for constructing artificial islands. Sites should be selected to avoid ice-rich permafrost. Laboratory tests may need to be conducted to determine the potential hazards of thaw consolidation and weakening.

VEYS, BEAUFORT SEA.

Artificial islands and gravity- and pile-founded towers used for the exploration and production of petrofeum resources in the Alaskan Beaufort Sea will be affected by conditions not found in more temperate waters. The force of sea ice, the thawing of subsea permafrost, and seasonal freezing and thawing all may cause failure of the foundations of these structures. To ensure the stability of foundations and fill structures, special precautions must be taken in selecting sites and evaluating the engineering properties of sea bed and fill materials.

IDENTIFYING AND DETERMINING HALO-CARBONS IN WATER USING GAS CHROMA-TOGRAPHY.

Leggett, D.C., Oct. 1981, 13p., ADA-108 345, 50 refs.

WASTES, WATER CHEMISTRY, HYDROCAR-BONS, CHEMICAL ANALYSIS.

BONS, CHEMICAL ANALYSIS.

Since the discovery that chloroform and other haloforms are produced during water chlorination, methods have been needed for their routine analysis. This report describes application of the multiple equilibration headspace technique for the determination of halocarbons in water. This method has certain advantages over solvent extraction and direct injection techniques, including greater sensitivity because of the favorable gas/liquid distribution ratios. It is simpler and faster than purge and trap and resin sorption methods and gives more information about compound identity than single headspace analysis because gas/liquid distribution ratios are determined experimentally. The method is absolute, unlike solvent extraction, resin sorption, purge and trap, and conventional headspace analysis, which require standard additions to correct for incomplete recovery. The use of the technique to analyze chlorinated water samples for haloforms revealed a potential problem in their analysis Haloforms continued to form for 24 hours, even after destruction of chlorine residuals with thiosulfate. Maximum haloform concentrations were observed in undechlorinated samples only after a 48-hour aging period. only after a 48-hour aging period.

SYNOPTIC METEOROLOGY DURING THE SNOW-ONE FIELD EXPERIMENT.

CAL DATA, SNOWFALL, MEASURING IN-STRUMENTS, MAPPING.

STRUMENTS, MAPPING.

The daily atmospheric pressure systems and weather fronts that traversed the northeastern United States during the SNOW-ONE Field Experiment from 11 January through 20 February 1981 are summarized. This experiment is first in a planned series of measurements to study the influence of atmospheric obscurants on electro-optical system performance. The analysis of the large-scale synoptic patterns that developed during the field test period constitutes a critical component of the research program. The weather during the measurement period included nine new daily high temperature records. January was one of the driest and February was one of the wettest ever observed. These conditions were caused in part by two high pressure cells and two major low pressure systems that crossed the region One of these lows brought warm air and heavy rain to New England, and the other produced significant snowfall in northern Vermont.

SITE SELECTION METHODOLOGY FOR THE LAND TREATMENT OF WASTEWATER Ryan, J.R., et al, Nov. 1981, 74p., ADA-108 636, Refs.

p.46-49.

Loehr, R.C.

36-1853 WASTE DISPOSAL, WATER TREATMENT, LAND RECLAMATION, SITE ACCESSIBILITY. AND RECLAMATION, SITE ACCESSIBILITY. A methodology is presented that covers facets of site selection from preliminary screening to field data acquisition for the preparation of a final design for a land treatment system. The basic assumption underlying the methodology is an approach to site selection in which the entire study area is investigated for potential sites while considering the whole spectrum of land treatment processes. Due to the extensive nature of such a study, several iterations are required to determine the most feasible site and land treatment alternatives. The methodology is presented in three parts. Level I defines the technical feasibility of implementing land treatment of a particular wastewater problem. The boundaries of the study area are defined and available land areas are rated for their suitability for land treatment based on topography, land use, hydrogeology and soil characteristics. A preliminary design for each suitable level I site candidate is prepared in the level II site analysis. The design is based on an evaluation of soil 'waste interactions that consider responses to limiting soil conditions. A cost-effectiveness evaluation of waste treatment alternatives and site candidates. responses to limiting soil conditions. A cost-effectiveness evaluation of waste treatment alternatives and site candidates is developed in level II. The most cost-effective site candidate is the selected for intensive level III field investigations. Data acquired in the level III field investigations will determine the design requirements of the land treatment

PREDICTING WHEELED VEHICLE MOTION RESISTANCE IN SHALLOW SNOW.

Blaisdell, G.L., Dec. 1981, 18p., ADA-147 117, 14

RUBBER SNOW FRICTION, SNOW COMPACTION, VEHICLE WHEELS, SNOW DEPTH, SNOW COVER EFFECT, TRAFFICABILITY, VELOCITY, FORECASTING, MATHEMATICAL

MODELS.

A vehicle traveling through snow is required to expend a greater amount of energy than is necessary when traveling on a rigid surface. Visually, this energy difference can be explained by the formation of a rut. Various attempts have been made in the past to equate the energy of compaction to vehicle motion resistance. However, many of the previous models use information gathered through the application of a vertical force (with a plate-sinkage device) to predict the horizontal motion resisting force. In an attempt to more accurately quantity the relationship between snow compaction and vehicle motion resistance, a vectorial analysis of compaction by a wiicel is performed. A method of using this compaction due to vehicle weight and forward thrust (horizontal propulsion) is suggested. Two methods of using this compaction force breakdown with field-generated data are proposed for the calculation of vehicle motion resistance in shallow snow.

SR 81.32 AUTOMOTIVE COLD-START MONOXIDE EMISSIONS AND PREHEATER EVALUATION.

Coutts, H.J., Dec. 1981, 37p, ADA-112 170, 7 refs.

ENGINE STARTERS, VEHICLES, COLD WEATHER OPERATION, AIR POLLUTION, TEMPERATURE EFFECTS.

TEMPERATURE EFFECTS.
Fairbanks and Anchorage, Alaska, experience high wintertime ambient levels of carbon monoxide (CO) Emissions from starting automobile engines in cold weather are thought to be a major source of CO. A quantitative procedure for determining startup CO was developed. The startup emissions were measured as a function of soak time at several low ambient temperatures. The performance of engine preheaters in reducing the startup CO at the various soak times and temperatures was estimated. The data scatter was too great to draw any firm conclusions, however, the length of cold-soak time appeared to have a stronger effect on cold-start CO emissions than dot soak temperatures (0 to -30C). Compared to no preheat, continuous preheat during an overnight cold soak can reduce the cold-start CO emissions by 20 to 90°C.

SR #1-33 SK 61-35 EFFECT OF SOIL TEMPERATURE AND PH ON NITRIFICATION KINETICS IN SOILS RE-CEIVING A LOW LEVEL OF AMMONIUM EN-RICHMENT.

Two soil samples from an on-going field study of land applica-tion municipal wastewater were spiked with low levels of ammonium to determine the effect of temperature on nitrificaammonium to determine the effect of temperature on nitrification kinetics. The concentrations of ammonium and nitriteplus-nitrate, and the number of autotrophic ammonium and
nitrite oxidizers were monitored periodically during the study.
There was a lag period prior to nitrite-plus-nitrate production
at all temperatures, and the length of this lag period was
temperature-dependent, with the longest period occuring at
the lowest temperature. The maximum rate of nitrification
increased with temperature as expected. While intriteplus-nitrate production appeared logarithmic, suggesting a
growing nitrifier population, the MPB counts of the nitrifiers
did not exhibit logarithmic growth. To study the effect
of soil pH on nitrification kinetics, soil samples from field
plots having the same soil type but different pHs (4 5, 5, 5,
and 7,0) were spiked with low levels of ammonium and
the rate of nitrite-plus-nitrate production was measured. The
maximum rate of nitrification was greater at pH 5.5 than
at 4.5. Unexpectedly rapid disappearance of ammonium,
nitrite and nitrate, caused by immobilization, obscured the
expected effects of pH on the nitrification rate at the highest
pH.

SEA ICE RUBBLE FORMATIONS IN THE BER-ING SEA AND NORTON SOUND, ALASKA. Kovacs, A., Dec. 1981, 23p., ADA-113 773, 22 refs.

PRESSURE RIDGES, ICE PRESSURE, SEA ICE, OFFSHORE STRUCTURES, ICE LOADS, ICE FORMATION, ICE SURFACE, OFFSHORE DRILLING, GROUNDED ICE, FLOATING ICE. The occurrence of large, compact, grounded pressure ridge formations up to 15 m high in the coastal waters of Norton Sound and the Bering Sea is discussed. These formations periodically float free and drift about, gouging the seabed. Their mass makes them a severe threat to both floating and bottom-founded structures in these waters

OVERVIEW OF MODELS USED IN LAND TREATMENT OF WASTEWATER.

Iskandar, I K., Mar. 1982, 27p., ADA-114 403, Refs. p.22-27. 36-2910

LAND RECLAMATION, WASTE TREATMENT, WATER TREATMENT, NUTRIENT CYCLE, MATHEMATICAL MODELS, SOIL MICROBIOLOGY, SOIL WATER, SOIL CHEMISTRY.

This report summarizes the state of the art of the modeling of wastewater renovation by land treatment. The models discussed are classified based on their use for planning, site selection and cost analysis, and for predicting 1) water and salt transport in soils, 2) nitrogen transport and transformations, 4) virus movement in soils, and 5) toxic metal and trace organic movement in soils. This report compares the different models as to their purpose, input and output data, and status of validation. In addition, the report includes a section on research needs for modeling land treatment of

CRYOLOGY, CHINA.

The Second National Chinese Conference on Permafrost was attended by the authors, and visits were made to two research institutes in Lanthou, the Northwest Institute of the China Academy of Railway Sciences and the Institute of Glaziology and Cryopedology. Appreut sately 100 papers were presented at the conference and 180 abstracts were presented at The papers were presented during three sessions 1). Distribution, Characteristics and Formation of Frozen Ground, 2) Basic Physico-Mechanical Properties and Processes in Frozen Soils, and 3). Engineering Design and Construction in Permafrest.

Sixty nine institutions conducting frozen ground research in China were represented. It was planned to present selected papers from this conference at the Foarth International Conference on Permafrost in Fairbanks, Alaska, in 1813.

SR 82-04 PRELIMINARY ASSESSMENT OF THE NUTRI-ENT FILM TECHNIQUE FOR WASTEWATER TREATMENT.

WASTE TREATMENT, WATER TREATMENT, SANITARY ENGINEERING, PLANTS (BOTANY), GROWTH, STATISTICAL ANALYSIS.

An experiment was conducted to determine the feasibility An experiment was conducted to determine the feasibility of using a solar powered, self-regenerating plant growth system, called the nutrient film technique (NFT), to treat primary effluent (average temperature, 11 C) Primary effluent was pumped onto the elevated end of a sloping waterproof 2-x40-ft plywood tray and trickled through the root mat of reed canary grass. The quantity of influent and effluent was measured as well as temperature, pH, total suspended solids, volatile suspended solids, BODS, total introgen, amounts nitrogen prirate attracts to the photonic absorbance in circumstant programments. solids, volatile suspended solids, BOD5, total nitrogen, ammonia nitrogen, nitrate nitrogen, total phosphorus, phosphate phosphorus, and fecal coliform organisms. The quantity and quality of the reed canarygrass was determined from samples taken from six harvests. Mass balances are presented for BOD5, total suspended solids, total nitrogen, ammonia nitrogen, total phosphorus, and phosphate phosphorus. The removal of several volatile trace organic compounds was determined on two separate dates.

PLANT GROWTH AND MANAGEMENT FOR WASTEWATER TREATMENT IN OVERLAND FLOW SYSTEMS.

Palazzo, A.J., Apr. 1982, 21p., 25 refs.

36-3113 WASTE TREATMENT, WATER TREATMENT, LAND RECLAMATION, PLANTS (BOTANY), GROWTH, GRASSES.

Domestic wastewater was applied over a four-year period at various rates to three overland flow test slopes to study forage grass growth and nutrient removal. The annual application rates of nitrogen and phosphorus ranged up to 2026 and 226 kg/ha, respectively. The forage grasses were harr-seted three times per season. Plant yields, composition and uptake of nutrients were determined. The results show that reed canary grass, quackgrass and Kentucky bluegrass were the most persistent grasses on the slope over the four

GRASSES, GROWTH, FLOODING, DAMAGE, PLANT PHYSIOLOGY, TESTS

PLANT PHYSIOLOGY, TESTS
Sis cold-adapted grasses were given ten-day dark and inundation stress treatments. Nugget Kentucky Nucgrass grown
in soil or gravel exhibited the best survival. Sydsport
bluegrass did well in gravel. Meadew fostail and manchar
brome survived the treatments when grown in silt soil, but
did not when grown on gravel soil. Ritionies were regenerated by most of the grasses. Root transverse sections
did not show any stress-related damage, but leaf sections
did. The damage in the sections paralleled that observed
macroscopically. Electrophoretic analysis for the perovidase
enzyme complex showed significant banding pattern differences before external damage was visible. This technique
may prove to be a diagnostic toos for determining stress
damage. Seedlings of all grasses except sydsport Niuegrass
survived. a 15-day inundation.

SR 82-13 IMPROVING ELECTRIC GROUNDING IN FROZEN MATERIALS.

Selimann, P.V., Arcone, S.A.

PERMAFROST PHYSICS, ELECTRICAL GROUNDING, ELECTRICAL RESISTIVITY, SA-LINE SOILS, GRAIN SIZE, ELECTRIC CHARGE, FROZEN GROUND PHYSICS, TESTS.

FROZEN GROUND PHYSICS, TESTS.

This study shows that resistance to ground of a simple vertical electrode in frozen fine-grained soil can be lowered significantly by placing it in a hole backfilled with a conductive soil-salt mixture. These tests were performed near Fairbanks, Alaska, in perennially frozen silt. Three electrodes were installed in holes created by detonating standard military shaped charges placed at the ground surface. The backfill contained varying amounts of salt. Measurement of resultance to ground was lowered by an order of magnitude by the addition of a water-saturated salt-soil backfill. Improvement persisted six months after the backfill was placed and allowed to freeze. The degree of improvement provided by this technique will be a function of grain size and permeability of the surrounding soil.

EVALUATION OF A SIMPLE MODEL FOR PREDICTING PHOSPHORUS REMOVAL BY SOILS DURING LAND TREATMENT OF WAS-TEWATER.

Ryden, J.C., et al, June 1982, 12p., ADA-117 848, 35

Syers, J.K., Iskandar, I.K. 36-4092

WASTE TREATMENT, WATER TREATMENT, SOIL CHEMISTRY, FORECASTING, LAND RECLAMATION, MATHEMATICAL MODELS.

This report evaluates a simple P balance model to predict site longevity with respect to P removal during land treatment of wastewater. The model is based on measured inputs and outputs of P at the treatment site and on an estimate of the P storage capacity of the soil profile. Sorption of P by three soils used for land treatment conformed to of P by three sous used for land treatment conformed to the P sorption model based on a generalized isotherm Laboratory sorption tests were used to predict P storage capacity of the soil profiles at a solution P concentration equivalent to that in the effluent applied to the soil. For two soil profiles the P balance model predicted site longerates of approximately 50 and 210 years. The existing depth of P enrichment in these profiles predicted from the model agreed closely with measurements of P enrichment based on amounts of NaOH-extractable P and on measured soil rolution P concentrations

LIMNOLOGICAL INVESTIGATIONS: KOOCANUSA, MONTANA. PART 4: FACTORS CONTROLLING PRIMARY PRODUCTIVITY. Woods, P.F., et al, June 1982, 106p., ADA-119 328, Refs. p.54-63.

BIOMASS, RESERVOIRS, LIMNOLOGY, DAMS, PHOTOSYNTHESIS, LAKE WATER, WATER TEMPERATURE.

TEMPERATURE.

Postimpoundment loadings of total nitrogen and total phosphorus delivered to Lake Koocanusa by the principal inflowing stream, the Kootenai River, were predicted to be large enough to cause cutrophication of the lake; however, measured annual primary productivity for 1972 through 1075 was relatively low, and characteristic of oligotrophic values because phytoplankton photosynthesis was suppressed by physical limnological factors. The predominant flood-control function of the reservoir necessitates substantial reductions in volume during the autumn and winter. These large-scale water movements weakened the thermal structure of the reservoir

Cragin, J.H., Aug. 1982, 9p., ADB-068 594, 3 refs.

AEROSOLS, SNOW COMPOSITION, SNOW SURFACE, AIR POLLUTION, CHEMICAL PROP-ERTIES, SMOKE GENERATORS.

Concentrations of orthophosphate, IR1 and IR2 obscurants were measured in surface snow samples after a winter test of white phosphorus (WP) smoke and the two infrared screeners. Sample concentrations of IR1 and IR2 decreased ers. Sample concentrations of 1R1 and 1R2 decreased exponentially downwind from the smoke release point. Orthophosphate concentrations were all lower than the analytical detection limit of 0.15 mg/L. Quantities of smoke released pose no hazard to the public or environment Snow was found to provide a clean non-contaminating surface upon which to collect the deposited aerosol.

LIMNOLOGY, LAKE WATER, DAMS, WATER POLLUTION, RESERVOIRS, NUTRIENT CYCLE, UNITED STATES—MONTANA— KOOCANUSA, LAKE.

KOOCANUSA, LAKE.

This report documents the effects of the construction of Libby Dam upon the water quality of the United States portion of the Kootenai River during the pre-impoundment phase of a long-term water quality study. Water quality problems during dam construction appeared to be restricted to short-term increases in suspended sediment and turbidity which suppressed the aquatic insect population in the rier downstream. Abnormally high background concentrations and abrupt chemical changes in water quality during the course of the study were attributed to industrial discharges from a fertilizer plant and mining operation located on an upstream inhutary to the river. Nutrent loadings of nitrogen and phosphorus were found to be of sufficient magnitude to grediet the development of cutrophic conditions following impoundment suggesting that effects in controlling nutrient impoundment suggesting that efforts in controlling nutrient point sources be continued

PILOT-SCALE EVALUATION OF THE NUTRI-ENT FILM TECHNIQUE FOR WASTEWATER TREATMENT.

Bouzoun, J.R., et al, Nov. 1982, 34p., ADA-123 429,

12 refs. Diener, C.J., Butler, P.L.

WASTE TREATMENT, WATER TREATMENT, CHEMISTRY, NUTRIENT CYCLE, PLANT PHYSIOLOGY, WATER RETENTION.

PHYSIOLOGY, WATER RETENTION.

An experiment was conducted to determine the feasibility of using several plant species in a pilot-scale nutrient film technique (NFT) installation to further treat primary-treated effluent. The reduction of biochemical oxygen demand, total suspended solids, and nitrogen and phosphorus concentrations by the NFT is discussed. Tracer studies showed that the hydraulic retention time of the wastewater in the NFT trays was inversely related to the wastewater application rate, and that for a given flow, plants with fine root systems (such as reed canarygrass) had a much longer detention time than plants with coarse tuberous rhizomes (such as cattails). The BOD reduction could be described using the plug-flow reactor model with first-order kinetics.

PHYSICAL PROPERTIES OF THE ICE COVER OF THE GREENLAND SEA.

Weeks, W.F., Nov. 1982, 27p., ADA-123 712, 3 refs.

ICE PHYSICS, SEA ICE, ICE STRUCTURE, ICE COMPOSITION, ICE MECHANICS, ICE FRICTION, ICE ADHESION, ICE ELECTRICAL PROPERTIES, ICE THERMAL PROPERTIES, FAST ICE, PACK ICE, GREENLAND SEA.

There is very little information available on the physical properties of the ice cover of the Greenland Sea. This pager reviews what is known about the different types of ice that are believed to occur in this area. It also discusses ice that are believed to occur in this area. It also discusses how the internal structure and composition of these ice masses may differ from those of the more extensively studied ice of the Beaufort Sea and identifies gaps in the present knowledge of the properties of such ice masses (regardless of places of origin). Finally a strategy is outlined for efficiently studying the properties of the ice in the Greenland Sea by combining structural and compositional characterization with limited property determinations.

RESERVOIR BANK EROSION CAUSED AND INFLUENCED BY ICE COVER.

Gatto, L.W., Dec. 1982, 26p. ADA-124 508, Refs. p.20-26

BANKS (WATERWAYS), SOIL EROSION, ICE EROSION, RESERVOIRS, ICE COVER EFFECT, EROSION, WATER LEVEL, BEACHES.

EROSION. WATER LEVEL BEACHES.
The purpose of this stud, was to evaluate the importance of reservoir bank crosson caused by an see over. The evaluation is based on a literature review and on inferences made from field observations and experience. Very little is known about the amount of reservoir bank crosson caused by the actions of an see cover, although considerable information is available on the processes of see-related erison along the shorelines of beaches of occani, mers or lakes. The importance of see-related erison along a reservoir bank seems to be determined primarily by water level. If the reservoir water level is high enough for see to act directly on the bank face, the amount of erisons caused by see could be substantial. If the water level is below the bank, ice would have no direct effect on it. However, see could indirectly increase bank instability by disrupting and erising nearsbore and brach zones, which could lead to bank crosson.

SR 82-32 DEVELOPING A WATER WELL FOR THE ICE BACKFILLING OF DYE-2.

One proposal to extend the useful life of DEW Line Ice
Cap Station DYE-2 is to backfill the lower 50 feet of the
truss enclosure with ice
This report discusses a method
by which 2.8 million gallons of water would be collected
and stored by melting ice. Also included is a description
of required components, their costs and the logistical requirements to establish such a system.

INFRARED INSPECTION OF NEW ROOFS. Korhonen, C., Dec. 1982, 14p., ADA-125 502, 9 refs.

ROOFS, MOISTURE DETECTION, INFRARED PHOTOGRAPHY, THERMAL INSULATION, BUILDINGS.

BUILDINGS.

The feasibility of using infrared cameras to detect wet insulation during the typical 1-year warranty period for new Army roofs was studied. Both the ability to gain moisture and the manner of wetting of insulations were of major concern. Although some insulations take on moisture much slower that others, \$ to 10 months usually is ample time for most insulations to absorb enough moisture to be detectable by an infrared camera. However, the early signs of this moisture as seen with the infrared camera differ with insulation type. Basically, boards of slower-westing cullular plasticmosture as seen with the intrared camera differ with insulation type. Basically, boards of slower-wetting cullular plastic insulations initially wet at their perimeters, whereas highly absorbent fibrous insulations tend to wet more or less uniformly. An infrared camera is well suited for finding the typically small and sometimes irregularly shaped wet areas on a new roof. A specification incorporating this technology should be now tested.

The flow routing model of the National Weather Service entitled DWOPER (Dynamic Wave Operational Forecast Program) is examined with regard to the modifications required to include the effect of river ice on the flow variables of water level and discharge the ice effects are described.

Difficulties in modeling the ice effects are described. Example model output is presented showing the transient effects introduced by imposition of removal of the ice cover from and otherwise uncovered flow.

CRREL INSTRUMENTED VEHICLE: HARD-WARE AND SOFTWARE.

Blaisdell, G.L., Jan. 1983, 75p., ADA-128 713.

18-4041 TIRES, VEHICLES, LOADS (FORCES), SURFACE PROPERTIES, TESTS, COMPUTER PROGRAMMEASURING INSTRUMENTS, MAIN MAINTE. NANCE, VELOCITY.

NANCE, VELOCITY.
This report gives a detailed description of the CRREL Instrumentate white (CIV) — The CIV is equipped with instrumentation to measure three mutually perpendicular forces acting at the interface between the front tires and any surface material. In addition, accurate wheel and white speed and rear sale torque are measured. The vehicle is equipped for front-wheel, rear-wheel of four-wheel drive. A dual brake system allows front-, rear- or four-wheel braking. A minisomputer-based data acquisition system is installed in the vehicle to control data gathering and to process the data. The software for data acquisition and manipulation and the interfacing techniques required are described.

This report discusses the results of an experiment to determine the effect of five factors on the load transferred through frozen soil to a buried land mine. The five variables examined were load, temperature, number of freeze-thaw cycles, soil, and water content. Analysis of a half-fraction factorial experiment shows that no one variable can be used as a predictor of mine functioning performance.

AGRICULTURE.

AGRICULTURE.

The material presented in Part 1 is intended to provide insight into the possible land treatment planning objectives, the status of land treatment research and implementations of these systems, and the potential for optimizing the configuration of these components.

The structure and application of nine models, which include methods to optimize the regional planning, design and operation of slow-rate land treatment systems, are briefly discussed. General comments follow on the overall status of research in land treatment modeling and design and directions for future work,

WASTE TREATMENT, WATER TREATMENT, SANITARY ENGINEERING, LAND RECLAMA-TION, BIBLIOGRAPHIES.

This bibliography contains publications of research funded in whole or in part by the Corps of Engineers Land Treatment Research Program, conducted from January 1972 to May 1982. The program was officially complete in October 1980. Six types of publications are included: 1) publications in open literature (which may include papers in journals, chapters in books and books), 2) technical reports, 3) engineer technical letters, 4) draft translations (mainly from Russian), 5) theses and dissertations (M.S., Ph.D.), and 6) presentations at scientific conferences. at scientific conferences

SR #3-10

SYNOPTIC METEOROLOGY DURING THE SNOW-ONE-A FIELD EXPERIMENT.

Bilello, M.A., May 1983, 80p., ADA-134 888, 8 refs. 38-885

SNOWFALL, STORMS, FREEZING, SYNOPTIC METEOROLOGY, PRECIPITATION (METEOROLOGY), METEOROLOGICAL DATA.

The daily atmospheric systems and weather fronts that traversed the northeastern United States during the SNOW-ONE-A Field Experiment from 30 November to 20 December 1981 and from 3 January to 10 February 1982 are summarized. This experiment is the second of a series of winter measure-This experiment is the second of a series of winter measurements of the influence of atmospheric obscurants on electrooptical system performance. The analysis of the large-scale synoptic weather patterns that developed during the field test period constitutes a critical component of the research program. Precipitation in northern Vermont during SNOW-ONE-A was near normal for the region. Numerous separate snowfall events, including some with substantial amounts of snow, were recorded during the experiment period. Although the storms that produced more than 6 cm of snow resulted from coastal cyclogenesis or developing waves that deepened as they moved north or northeastward waves that deepened as they moved north or northeastward waves that deepened as they moved north or northeastward along the Atlantic coastline. The majority of the other events with lighter amounts of freezing precipitation were caused by less intense storm systems, troughs, or fronts that traversed the region from the west or northwest and often moved quite rapidly.

EFFECT OF VESSEL SIZE ON SHORELINE AND SHORE STRUCTURE DAMAGE ALONG THE GREAT LAKES CONNECTING CHAN-NELS

Wuebben, J.L., May 1983, 62p., ADA-134 887, 13

40-4677 SHORES, CHANNELS (WATERWAYS), ICE LOADS, SHIPS, STRUCTURES, DAMAGE, VELOCITY, GREAT LAKES.

In conjunction with the Great Lakes connecting channels In conjunction with the Great Lakes connecting channels and harbors study, this report examines the potential damage to the shore and shore structures due to an increase in vessel size. The areas considered in this report are the United States shorelines along the St. Marys, St. Clair and Detreit rivers. The potential for shoreline or shore structure domage due to an increase in vessel size was reviewed on both a conceptual and site-specific basis. Ship-induced warest were ruled out as a damage mechanism since the on both a conceptual and site-specific basis. Ship-induced waves were ruled out as a damage mechanism since the analysis showed that the contemplated increases in vessel size would not significantly affect wave heights in the nearshore zone. Propeller wash was discounted for similar reasons Ship-induced drawndown was determined to be the major potential damage mechanism. While larger ships potentially produce more damage, this potential is significant only in severely restricted channel sections for the size increase considered here. By far the most significant factor in sub-prelated damage potential is vessel speed. In almost all areas the effect of an increase in vessel size could be eliminated by a reduction in vessel speed of 1-2 mph.

SHORELINE EROSION AND SHORE STRUC-TURE DAMAGE ON THE ST. MARYS RIVER. Wuebben, J.L., May 1983, 36p., ADA-134 863, 4 refs. 32.226

SHORELINE MODIFICATION, SHORE ERO-SION, FAST ICE, SEDIMENT TRANSPORT, STRUCTURES, DAMAGE, ICE NAVIGATION, ICE FLOES. PIERS.

ICE FLOES, PIERS.
From 1961 to 1970 navigation on the St. Marys River closed for the winter from mid-December to mid-April. Subsequent extension of the navigation season to include the winter months resulted in complaints of shoreline and dock damage along the navigation channels. Studies were initiated to examine the potential for navigation-caused damage, but information on damage during a navigation-free winter was lacking. Since limited navigation was planned during the 1979-80 winter, the St. Marys River System could be examined under relatively undisturbed conditions. The report examines potential navigation-related damage mechanisms and persents data from the closed navigation season. The results are compared with information collected during previous periods with winter navigation.

FROZEN GROUND STRENGTH, LOADS (FORCES), UNFROZEN WATER CONTENT, SOIL WATER, TEMPERATURE MEASURE-MENT, NUCLEAR MAGNETIC RESONANCE, THERMODYNAMICS.

THERMODYNAMICS.

Frozen samples of a Manchester silt having various total water contents were subjected to several surcharge loads, and the unfrozen water content was measured with NMR as the temperature was gradually raised. The surcharge pressure had a greater effect on the unfrozen water content than had been predicted using the Clausius-Clappyron equation. This effect was explained by considering the loaded samples as nonequilibrium systems in which the surcharge pressures were concentrated in the ice phase.

EXAMINATION OF A BLISTERED BUILT-UP ROOF: O'NEILL BUILDING, HANSCOM AIR FORCE BASE.

Korhonen, C., et al, June 1983, 12p., ADA-133 042, 2 refs.

Greatorex, A

ROOFS, DEFORMATION, COLD WEATHER TESTS, MOISTURE, INFRARED SPECTROS-COPY.

Blisters are a common defect in built-up roofs. In January 1983 we examined a recently constructed built-up roof at Hanscom Air Force Base in Bedford, Massachusetts, to deter-mine the cause of its blisters. We used an infrared scanner, mine the cause of its blisters. We used an infrared scanner, took ten core samples, conducted visual examinations, and cut open three blisters. Our findings show that the membrane is essentially watertight and that the blisters were caused by voids that were built into the roof during construction. Poor workmanship and cold weather are the likely exauses of the voids. With proper maintenance reasonable performance can be achieved from this imperfect roof

SR 83-22 ESTIMATING TRANSIENT HEAT FLOWS AND MEASURING SURFACE TEMPERATURES OF

A BUILT-UP ROOF. Korhonen, C., July 1983, 20p., ADA-133 043, 4 refs.

HEAT TRANSFER, SURFACE TEMPERATURE, ROOFS, INFRARED EQUIPMENT, THERMAL INSULATION.

Transient heat flow through a multilayered building component can be estimated using the transfer function method presented in the ASHRAE (1977) Handbook of Fundamentals. Solin the ASHRAE (1977) Handbook of Fundamentals. Sol-air temperature is one parameter recommended for use in this method, but surface temperatures were shown to be a reasonable substitute. Although the magnitude of the heat flow as calculated with the transfer function appears to be reasonable, more testing should be carried out to determine its accuracy. An infrared camera can measure roof surface temperatures fairly accurately; the most accurate measurements were made at night.

AEROSTAT ICING PROBLEMS

METEOROLOGICAL INSTRUMENTS, SURING INSTRUMENTS, SHIPS, I MEA-BOOMS (EQUIPMENT). ANTARCTICA

(EQUIPMENT). ANTARCTICA

We have developed a simple boson for use in measuring meteorological variables from a shap. The main structural member of the boson, a triangular communications tower with rollers attached along its bottom side, is deployed horizon atth from a long, first deck, such as a holocopter deck, and will support a 100-lig payload at its outboard end. The boson is easy to deploy, requires minimal ship modifications, and provides ready access to the instruments mounted on it. And because it is designed for use with the ship recommand, occanographic work as an go on at the same time as the air-sea interaction measurements. We detectibe our use of the boson on the Mikhazi Somon during a crisic into antarctic sea see and present some representative measurements made with instruments mounted on it. Theory, experiment, and our data all imply that instruments deployed windward from a rear helicopter deck can reach air undisturbed by the ship. Such an instrument with has clear advantages over the more customary mast, bon, or busy locations (Auth.)

SHIP ICING, ICE CONDITIONS, ICE FORMATION, ICE PREVENTION, PROTECTIVE COATINGS, OFFSHORE DRILLING, SHIPS, SEA SPRAY

A semishmerable dailing vessel (SFDCO 105) was equipped with see detectors and see accretion measurement devices, and showers attended the accretion measurement devices, and shower attended an exportatory well on the North Assurant Shelf. One significant storm

occurred 2-8 January 1983, which resulted in light spray ice accretion, estimated at 30 tons and a maximum thickness of 5 in. on understructure diagonal trusses. Only minor of 5 in. on understructure diagonal trusses. Only minor icing (less than 1 in.) occurred on the windward takin columns (30 ft diameter). Comparison with the 1979 Occan Bounty icing event suggests that wind speed is the significant parameter influencing icing severity, and that light icing will occur at average speeds around 30 knots and heavy icing around 88 knots, with undefined severity within the range. Four irephobic cruttings were exposed on test panels, one was effective

From 15 January through 15 April 1932, the U.S. Combat Support Boat (USCSBMK I) was tested on the Connecticut River, in and around Hanover, New Hampsbure, to examine niver, in an amount element; were transporter, in examine the operation on an rescontered waterway. The objectives were to determine to what extent shoreline see a ould affect were to determine to what extent shortene are a-ordel affect limitch and recovery and if the boat could create an architectural across a river so that a ribbon-bodge could be floated. Shortene are can inhibit limitch and recovery, but several solutions were developed to reduce or chrimate these problems. The boat can, to a limited extent, he med as an expedient secheraler. It can break competent see shorts 35-4 in thick as well as significantly thicker than-weakened see shorts. Shorts of well degraded and of season, see up to 10 in thick were broken.

MODEL TESTS IN ICE OF A CANADIAN COAST GUARD R-CLASS ICEBREAKER.

Tatinelaux, J.C., Apr. 1984, 24p., ADA-141 995, 13

ICEBREAKERS, ICE COVER STRENGTH, ICE NAVIGATION, ICE FRICTION, STRENGTH, MODELS, TESTS, ICE SOLID INTERFACE, PRO-PELLERS, FORECASTING, VELOCITY

This report presents the results of resistance and propulsion tests in level see of a 1 Thirade model of the Rocassi scheeder of the Canadian Coast Guard. On the basis of the model of the Canadan Coast Grand. On the basis of the model test results, folloscale performance is predicted and compared with available find-scale trials data. Predicted or creastance and required peopoles spin, thrust and delivered power are lower than full-scale measurements. Dus disagreement was attributed to the fact that the ship model had a much lower see friction crefficient than the prototype. On the other hand, predictions of thrust and power for a given ship speed and propeller spin are in good agreement with corresponding full-scale measurements.

GREENLAND.

On July 22 1983 a dozen reinforced concrete buildings, built in 1954 at Sondrestrom Air Base in Greenland, were examined to determine why their concrete wall panels were cracked, spalled and rest stained. The investigation determined that structural and thermal movements caused most of this deterioration. Very little freeze-than deterioration was evident on the omiside, but the most serious problem was that of frost damage within the wall cavities fed by moistine from the inside of each building. The visible surface defects can be repaired with breathable patching materials, but to achieve long-term success and to minimum wall-cavity frost damage, vapor impraison through the walls must be properly controlled.

39-561

GROUNDING, ELECTRICAL RESISTIVITY FREEZE THAW CYCLES, FEB. 17007 PHYSICS, SALINE SOILS, GRAIN SIZE, SOIL TEMPERATURE, GROUND ICE, TESTS.

PERATURE, GROUND ICE, TESTS.

This report describes two new methods for computing borehole geometry from discrete measurements of borehole inclination and azimuth. Ir 'ee first method borehole inclination and azimuth are solved to vary linearly with arc length. This results in an analytic model of the borehole that is continuous but not smooth. The second model, which takes borehole inclination and azimuth to vary quadratically with arc length between three measuring points, improves the smoothness of the model but the analysis must be carried out numerically. These models were applied to the installations. In all cases salt backfilling reduced the resistance to ground, with 175 ohns being the lowest obtained. Reductions varied from very small to an order of magnitude, Resistance also decreased over several seasons. Generally, the greatest improvement and lowest values were obtained in t'e perennially frozen silt in interior Alaska. Data from older silt suggest that salt backfilling will not be effective in arctic settings. Measurements at a partially thaved, coarse-grained site indicate that salt was moving much more rapidly (approximately five times as fast) away from the treated backfill than at the silt site in the CRREL permafrost tunnel. permafrost tunnel.

MILITARY RESEARCH, COLD WEATHER TESTS, MINES (ORDNANCE), RADAR ECHOES, COUNTERMEASURES, GROUND GROUND THAWING.

THA WING.

The interaction among UHF radiation, winter roadway conditions and buried mines was investigated in a refrigerated facility. The near-field spatial return from each target was unique. When the target was not in the near field the spatial return was not at all unique Cobbles in the medium had little effect, but surface-thawed conditions significantly affected the carried returns and the effect of the effect o medium had little effect, but surface-thawed conditions significantly affected the spatial return, and the reflected signal strength and frequency content. The primary frequency content of the returned signal was either spread over a band broader than that of the transmitted primary frequencies, or simpletely outside of the primary detection band. We conclude that the complexity of winter roadway conditions requires 1) a much broader frequency band than is currently being considered, and 2) a more complex and edaptive background-removal, signal-enhancement scheme than is currently used. Further, more data are required describing the interaction of the winter media, UHF radiation, and buried mines so that adequate detection instrumentation can be developed

BUCKLING ANALYSIS OF CRACKED, FLOAT-ING ICE SHEETS.

CRACKING (FRACTURING).

Serious deterioration of concrete bridges by deicing salts is generally ascribed to depassivation and corrosion of reinforcing steel, as growth of its corrosion products causes spalling, there, simple evaporative tests simulated the salt weathering that slowly crumbles rocks in nature, where crystals growing from pore water fed from below stress the matrix just as do ice crystals in frost heaving soil. Like needle ice (surface frost action in soil) the salt columns exuded from concrete alro lifted tmy particles, signifying crumbling Microcracks developed in 1-3 years of after-test dry storage.

SECONDARY STRESS WITHIN THE STRUC-TURAL FRAME OF DYE-3; 1978-1983. Ueda, H.T., et al, Sep. 1984, 44p, ADA-148 401, 5

refs.
Tobiasson, W., Fisk, D., Keller, D., Korhonen, C.

CONSTRUCTION, GREENLAND.

DEW line ice cap station DYE-3 was moved sideways 210 ft and placed on a new foundation in 1977, then raised 27 ft in 1978. Secondary forces within the structural steel framework were measured in 1978, 1981, 1982 and 1913. The overall level of secondary stresses had increased but through 1983 the columns were still within their stress limitations. Some localized overstress is expected in 1984. The concept of using above-surface trusses to resist wind loads and brace the eight columns has proven to be satisfactory. It has climinated the subsurface enclosures used in the past to protect subsurface trusses, enclosures that proved to be the structural weak link of the original facility, their elimination has resulted in a stronger facility that is easier to maintain The measurements and findings of this program were used in the development of the design to extend the life of DYE-3 to be implemented in 1984. That work should reduce the level of secondary stresses in the frame. CONSTRUCTION, GREENLAND.

DEUTERIUM DIFFUSION IN A SOIL-WATER-ICE MIXTURE.

ROAD MAINTENANCE, BITUMINOUS CONCRETES, COMPACTION, EQUIPMENT, DENSITY (MASS/VOLUME), TEMPERATURE EFFECTS.

FECTS.

This report is a summary of the results of a compaction study using recycled hot mix asphalt concrete conducted during August 1983 in an indoor facility at CRREL in Hanover, New Hampshire. This study compared three kinds of compactors for optimum performance, and also considered such factors as temperature of the asphalt concrete mix, number of passes, size and depth of patches, and the number of lifts to fill the holes Results showed that a vibratory roller and vibratory plate compactor could both compact patches to the desired 98% of laboratory density, but that a 200-lb lawn roller could not Temperature of the hot recycled mix is entical, with 205P being the cut-off temperature. It was shown that if the mix is not compacted promptly after placement and is allowed to cool below 250F, proper compaction may not be attained.

FROZEN PRECIPITATION AND CONCUR-RENT WEATHER: A CASE STUDY FOR MUN-CHEN/RIEM, WEST GERMANY.

VARIATIONS, USSR.

A survey of the Cold Regions Science and Technology Bibliography and other references in the CRREL library was conducted to compile recent information about several Soviet physiogeographic features: permafrost, seasonally frozen ground, snow cover and vegetation. The products of the study are 1) a series of maps presenting the general distribution of these features over the entire Soviet Union and 2) a collection of 57 maps showing the local distribution of ground ice and permafrost.

OVERVIEW OF TANANA RIVER MONITOR-ING AND RESEARCH STUDIES NEAR FAIR-

BANKS, ALASKA. Neill, C.R., et al. Jan. 1984, 98p. + 5 appends.. ADA-167 790, Refs. passim For individual articles see 38-4207 through 38-4211.

STATES—ALASKA—TANANA RIVER

STATES—ALASKA—TANANA RIVER
The Tanana River changes character in the vicinity of Fairbanks, from the braided pattern upstream of North Pole to the anastomosing or irregular meander pattern downstream of the Chena River confluence. This transition in planform is accompanied by a marked decrease in gradient and a change. I dominant bed material from gravel to sand. Within the past 50 years the river has been affected by a variety of human activities, including flood control works, access causeways and gravel extractions. The Phase III in-river levee and groin construction constituted a strong local disturbance of the river system where local inver slove was steepend. levee and groin construction constituted a strong local disturbance of the river system where local river slope was steepened and large quantities of bed material were put into transport from pilot channel enlargement as the river adjusted to the new alignment. As of the end of 1982, the full and final effects of this disturbance were not clear. Recommendations are given regarding impacts from human activities, alleviation of impacts, levee protection, further interpretive analysis and future monitoring of river behavior.

CATALOG OF CORPS OF ENGINEERS STRUC-TURE INVENTORIES SUITABLE FOR THE ACID PRECIPITATION-STRUCTURE MATERI-AL STUDY.

PRECIPITATION (METEOROLOGY), CHEMICAL PROPERTIES, CONSTRUCTION MATERIALS, ENVIRONMENTAL PROTECTION, DAMAGE, BUILDINGS, COST ANALYSIS, COMPUTER APPLICATIONS.

This report contains a survey of Corps of Engineers floodplain This report contains a survey of Corps of Engineers floodplain inventories. Its purpose was to determine if enough building materials information was available in the Corps data base to be used for predicting the distribution of building materials across the country as part of the EPA and rain assessment program. The floodplain surveys were rated using the criteria of the date of the surveys, the number of buildings, the variety of building materials, the amount of dimensions data listed for the buildings the land cover types in the Jata and whether or in the data were computerized. Six structure inventories are recommended for further study

SURVEY OF ICE PROBLEM AREAS IN NAVI-GABLE WATERWAYS.

Zufelt, J, et al, Apr. 1985, 32p., ADA-157 477. Calkins, D.J.

40-3360

40-3500 ICE NAVIGATION, ICING, LOCKS (WATER-WAYS), DAMS, ICE CONTROL, RIVER ICE, ICE CONDITIONS, ICE JAMS, ICE BREAKUP.

CONDITIONS, ICE JAMS, ICE BREAKUP.
This report presents the findings of a survey of ice problems encountered on the nation's major navigable waterways. A survey questionnaire was developed and, through a field review group, was distributed to lock and dam facilities on the Allegheny, Monongahela, Ohio, Kanawha, Kaskaskia, and Mississippi Rivers and the Illinois Waterway. Analysis of the completed questionnaires identified 13 ice problem categories. The report describes each category of ice problem encountered, as well as the cited methods, operational and/or structural, undertaken to reduce the impact of each ice problem.

PERIGLACIAL LANDFORMS AND PRO-CESSES IN THE SOUTHERN KENAI MOUN-TAINS, ALASKA.

Bailey, P.K., Apr. 1985, 60p., ADA-157 459, Refs. p 54-60. 40-764

PERIGLACIAL PROCESSES, LANDFORMS, PERMAFROST DISTRIBUTION, GEOMOR-PHOLOGY, PATTERNED GROUND, NUNATAKS, ALTIPLANATION, NIVATION, SOIL TEMPERATURE, UNITED STATES—ALASKAKENAI MOUNTAINS.

KENAI MOUNTAINS.

The distribution and characteristics of periglacial landforms in the southern Kenai Mountains, Alaska, were investigated during 1979 and 1980. The principal area of study was a 1300-m-high mountain mass that stood as a nunatak during the last general glaciation. Periglacial features in the area include gelifluction lobes, invation hollows, cryoplanation teraces, tors, a string bog, and such patterned ground as sorted circles, sorted polygons, earth hummocks, sorted steps, sorted stripes, and small ice-wedge polygons

USER'S GUIDE FOR THE BIBSORT PROGRAM FOR THE IBM-PC PERSONAL COMPUTER. Kyriakakis, T., et al, Apr. 1985, 61p., ADA-157 936. Iskandar, I.K. 39-4055

PROCESSING. BIBLIOGRAPHIES. DATA MANUALS, COMPUTER PROGRAMS, COM-PUTER APPLICATIONS.

PUTER APPLICATIONS.

This report is intended to provide the reader with step-by-step listructions on how to use the BIBSORT computer program on the IBM Personal Computer. The program allows storage and retrieval of bibliographic data. The program has been tested on an IBM-XT, using DOS 1.1 or 2.1. The program requires a monitor and a printer this user's guide discusses how to prepare diskettes to enter the data, how to name categories and files, how to open categories and files, and how to enter data. The guide also shows how to sort and store data, edit, delete, or append the data, and how to obtain a hard copy of the sorted data. Each data diskette can take up to 500 entiries, assuming 512 characters per entry. A section on how to change the program to fit specific needs is presented in Appendix A, and the program listing is in Appendix B.

CONSTRUCTION MATERIALS, PRECIPITA-TION (METEOROLOGY), CHEMICAL PROPER-TIES, BUILDINGS, RAIN, FORECASTING

TIES, BUILDINGS, RAIN, FORECASTING Data bases on buildings in Revere and Quincy, Massachusetts, and Stamford, Connecticut, were studied to determine if a measure of building maternal distribution could be calculated for a city using land use, census tract and the Corps' data on buildings. Statistical measures of chi-square, asymmetric lambda, uncertainty coefficient, F ordinate, as well as the correlation coefficient-squared and eta-swuared statistics were calculated for the three data bases The Corps definition of building type was found to be the best predictor of the building surface area. However, all indicators (including building type) explained only low percentages of the variability building type) explained only low percentages of the variability in the dependent variable (building surface area). These results indicate that other variables are required to explain the variability of building surface area adequately

SUITABILITY OF POLYVINYL CHLORIDE PIPE FOR MONITORING TNT, RDX, HMX AND DNT IN GROUNDWATER.

Parker, L.V., et al, Aug. 1985, 27p., ADA-160 733, Refs. p.19-22.

Jenkins, T.F., Foley, B.T. 40-1497

PIPES (TUBES), GROUND WATER, WATER POLLUTION, WATER CHEMISTRY, MATERIALS, TESTS, SALINITY.

POLLUTION, WATER CHEMISTRY, MAJERI-ALS, TESTS, SALINITY.

A number of samples of commercial PVC groundwater monitoring pipe, which varied in schedule, diameter or manufacturer, were placed in contact with low concentrations of aqueous solutions of TNT, RDX, HMX and 2.4-DNT for 80 days under nonsterile conditions. Results indicated that there was some loss of TNT and PMX in the presence of PVC pipe compared to glass controls but that for the most part concentrations of analyte were equivalent between types of pipe. A second experiment was performed to determine if the losses were due solely to sorption or if biodegradation was also a factor. This experiment was done under a variety of groundwater conditions by varying salinity, initial pH and dissolved oxygen. The only case where there was increased loss of any substance because of the presence of PVC pipe was in the TNT solution under nonsterile conditions. This increased loss was thought to be associated with increased microbial degradation rather than sorption. Therefore, given the length of time of this experiment and the small amount of loss attributable to sorption, PVC groundwater monitoring spipe is acceptable for monitoring groundwater for these munitions. Several samples of PVC pipe were also leached with groundwater for 80 days and no detectable interferences were found by reversed phase HPLC analysis.

CONSTRUCTION AND CALIBRATION OF THE OTTAUQUECHEE RIVER MODEL

Gooch, G., Aug. 1985, 10p., ADA-159 902.

ICE JAMS, ICE BREAKUP, RIVER ICE, ICE FOR-MATION, MODELS, FLOODING, WATER SUP-PLY. TESTS.

The Ottauquechee River is located in west-central Vermont. This river was chosen for a physical hydraulic model using real ice. The model was built at a scale of 150 horizontal and 1'20 vertical After problems with modeling bed rough-ness and operating the pump system were overcome, the tests went smoothly.

LOCATING BURIED UTILITIES.

Bigl, S.R., Sep 1985, 48p, ADA-213 084, 2 refs

UTILITIES. UNDERGROUND FACILITIES. MAGNETIC SURVEYS, DETECTION, EQUIP-

MENT.
This report describes, in basic language, how to operate buried-utility locators and what the locators' uses and limitations are. Its scope is limited to locators using the principles of magnetometry, induction balance, magnetic induction and radio-frequency tracking. Magnetometry and induction balance work best for near-surface isolated targets such as valve boxes and mainhole covers. Magnetic induction will locate all types of metallic utilities, including cast iron and steel pipe, power cables and communication lines. Radio-frequency tracking traces unpressurized non-metallic lines that have available access for introducing a floating transmitter into the line (e.g., sewer or storm drains made of plastic or vitreous tile pipe).

Foley, B.T.

40-4456

SOIL CHEMISTRY, SEDIMENTS, METALS, DE-TECTION, CHEMICAL ANALYSIS, DRYING.

Mercury in soils and sediments can be accurately determined over the concentration range of 0.04 to 2 microgram Hg/g using amalgamation on thin gold films Relative standard deviation of analysis is about 10%. A mild sample dissolution technique, involving HNO3 at 75C, produced quantitative Hg recoveries for certified sediment samples and recoveries equivalent to those of ingorous Parr-bomb digestions for other soil and sediment samples. Oven drying of samples at 150C resulted in significant losses of Hg from both soil and sediment samples. Air drying, oven drying at 60C or freeze drying resulted in Hg recoveries that agreed within 20% of those for undried samples. Thus, any one of these three comparable methods is recommended for Hg determinations in soils and sediments Mercury in soils and sediments can be accurately determined

DETERMINING THE EFFECTIVENESS OF A NAVIGABLE ICE BOOM.

Perham, R E., Oct 1985, 28p, ADA-162 926, 19 refs. 41-446

ICE NAVIGATION, ICE BOOMS, RIVER ICE, ICE CONTROL, ICE COVER THICKNESS, ICE POROSITY.

POROSITY.

The performance of a navigable ice boom was studied by monitoring the progression of the leading edge of the unconsolidated ice cover over a reach of the St Marys River directly downstream of the boom lice and hydraulic data were obtained for four winters from 1975-76 through 1978-79 for the St Marys River at Sault Ste Marie, Michigan The ice cover progression rate was highest in early winter The unconsolidated ice cover in the channel was estimated to have a thickness of at least 0.91 m and a porosity of 30% During early winter the ice discharge per vesse passage averaged approximately 5500 cu m for the four years Model tests for this site had indicated that without an ice control structure of any type, an ice release of 63,000 an ice control structure of any type, an ice release of 63,000 cu m per ship passage could be expected, with an ice boom the release would be 12,300 cu m per ship passage.

SNOW IN THE CONSTRUCTION OF ICE BRIDGES.

Coutermarsh, BA, et al, Oct 1985, 12p, ADA-163 118, 6 refs.

Phetteplace, G. 40-3269

40-3269
ICE CROSSINGS, MILITARY OPERATION, SNOW (CONSTRUCTION MATERIAL), SNOW COVER EFFECT, SURFACE PROPERTIES, ICE SURFACE, ICE COVER STRENGTH.

SURFACE, ICE COVER STRENGTH.

Snow's contribution as a wearing surface, leveling material or reinforcement to ice bridges is discussed. It is shown that it has limited value as a reinforcement and then only by adding water and freezing the resulting slutry. Snow can be used effectively as either a leveling or wearing surface but natural ice thickening is inhibited by the insulating property of the snow. The snow should be of uniform depth and not mounded or windrowed to avoid deflecting the ice away from the water surface. This would substantially weaken the carrying capacity of the ice bridge. carrying capacity of the ice bridge

DESCRIPTION OF THE BUILDING MATERI-ALS DATA BASE FOR NEW HAVEN, CONNECT-ICUT.

Merry, CJ, et al, Nov. 1985, 129p., ADA-166 457, 13

LaPotin, P.J.

GONSTRUCTION MATERIALS, CHEMICAL PROFERTIES, SAMPLING, DAMAGE, STATISTICAL ANALYSIS, COMPUTER APPLICATIONS, PRECIPITATION (METEOROLOGY), ENVIRONMENTAL PROTECTION.

ENVIRONMENTAL PROTECTION.

A building material sampling program for the New Haven, Connecticut, region was conducted in March and April of 1984 to examine the types and amounts of building surface materials exposed to acid deposition. A stratified, systematic, unaligned random sampling approach was used to generate sample points across the five sampling frame areas. At least 107 sample points were examined per sampling frame to yield a total sample size of 576 points. Building sizes, surface materials, roof characteristics, roof-mounted apparatus, changings, suffers, downspouts, frees, and mixellaneous outsurface materials, fool characteristics, roon-mounted apparatus, chinneys, gutters, downspouts, fences and miscellaneous out-door accessories were recorded. This report provides an initial summary of the data collected. Sample sizes indicate that additional sampling is required to produce the desired 70 sites (with buildings) per frame.

SR 85-20 POTENTIAL OF REMOTE SENSING IN THE CORPS OF ENGINEERS DREDGING PRO-GRAM.

McKim, H.L., et al, Nov. 1985, 42p., ADA-166 334, Refs. p.23-37

Klemas, V., Gatto, L.W., Merry, C J.

DREDGING, REMOTE SENSING, AERIAL SUR-VEYS, CHANNELS (WATERWAYS), SEDIMENT TRANSPORT, SUSPENDED SEDIMENTS, ENVI-RONMENTAL IMPACT

RONMENTAL IMPACT.

The potential of remote sensing in the Corps of Engineers Dredging Program for providing data on channel surveys, sediment drift and dispersion during dredging, water quality and suspended sediment concentrations, and selection of disposal sites and monitoring environmental effects at disposal sites was reviewed. The recommended remote sensor combination for recording dredging and environmental changes was a small, single-engine aircraft equipped with at least two 70-mm or 35-mm cameras. The first camera should be loaded with color film and the second camera with color infrared film for vegetation or land use mapping, or panchromatic film with special filters for water studies. For bathymetric mapping, the cameras will have to be supplemented by airborne impulse radar or laser profilers, and possibly sonar depth finders. A combination of small aircraft and boats is optimum for mapping currents and observing plume dynamics.

IMPULSE RADAR SOUNDING OF LEVEL FIRST-YEAR SEA ICE FROM AN ICEBREAKER. Martinson, C.R., Nov 1985, 9p., ADA-163 229, 2 refs. 41-461

41-461
ICE COVER THICKNESS, SEA ICE, RADAR ECHOES, SOUNDING, ICEBREAKERS.
During the last weeks of May 1984, a CRREL impulse radar system was used onboard the RV Polarstern to measure the thickness of level first-year sea ice. The purpose was to determine the onboard performance of the radar system and, if possible, provide ice thickness information to researchers conducting other tests. Radar data were compared with ice thicknesses determined by drilling, indicating that radar soundings could be a viable means of collecting ice thicknesses information. A lack of adequate coordination between the two measurement methods prevented a point-by-point companison of ice thicknesses, the companisons were based on averages for particular test runs. The differences between the two measurement methods prevented a pointby-point comparison of ice thicknesses, the comparisons were
based on averages for particular test runs. The differences
of the averages from the two measuring methods ranged
from 0.03 m to 0.22 m with a mean variation in the differences
of 0.13 m for eight runs. There may have been some
interference from the ship's hull during data collection because
of the location of the antenna. However, an unidentified
signal in some of the data does not appear to obscure
a valid return from the bottom of the ice sheet

SR 85-22

COMPARISON OF EXTRACTION TECHNIQUES AND SOLVENTS FOR EXPLOSIVE RESIDUES IN SOIL.

Jenkins, TF, et al, Nov 1985, 33p., ADA-166 474, 11

Leggett, D.C. 40-3272

SOIL CHEMISTRY, EXPLOSIVES, SOIL POLLU-TION, ULTRASONIC TESTS, CHEMICAL ANAL-

YSIS.

Extraction of TNT, TNB, RDX and HMX from two soils was studied in terms of process kinetics and recovery. Two solvents, acetonitrile and methanol, and four extraction techniques. Soxhlet, ultrasonic bath, mechanical shaker and homogenizer-sonicator were compared. The results were complex in that some interactions among analyte, method and solvent were found. Acetonitrile was found to be clearly superior to methanol for RDX and HMX. Soxhlet and ultrasonic bath generally recovered more than homogenizer or shaker, although a complicating factor is that all techniques were not necessarily at equilibrium. In terms of sample throughput, the ultrasoric bath and shaker are preferred over Soxhlet and homogenizer-sonicator. The ultrasonic bath generally approached equilibrium more rapidly than the shaker so it appears to be the best overall choice. Another complicating factor is that times to reach equilibrium were different for the two soils and for the different analytes. This points to the need for more kinetic studies on other soils and sediments. soils and sediments

PRELIMINARY INVESTIGATIONS OF MINE DETECTION IN COLD REGIONS USING SHORT-PULSE RADAR.

Arcone, S A, Nov. 1985, 16p., ADB-100 401, 10 refs

40-3302
DETECTION, SNOW COVER EFFECT, RADAR ECHOES, MINES (ORDNANCE), DIELECTRIC PROPERTIES, FROZEN GROUND PHYSICS, POLARIZATION (WAVES), POLAR REGIONS.

Short pulse radar is being investigated as a tool for detecting mines in cold regions. The specific problem is the detection of mines buried in a snowpack characterized by a dielectric constant. In this preliminary investigation air and frozen

sand are used to roughly approximate the dielectric extremes of a dry snowpack. The radar signal used had a duration sand are used to roughly approximate the dielectric extremes of a dry snowpack. The radar signal used had a duration of 3-4 ns and a broad frequency spectrum centered near 800 MHz. The responses of mines suspended in air were first recorded as a function of polarization and orientation Mine responses were then recorded for emplacement in a fairly homogeneous dielectric of frozen sand. The waveform amplitudes depended strongly on mine orientation and weakly on polarization. Resonances in air at all orientations and polarizations for a particular mine type were similar. Responses in the sand were easily recognizable for an antenna standoff of 1 m, but depended on target size. in a snowpack are now beginning SR 85-24

REGRESSION MODELS FOR PREDICTING BUILDING MATERIAL DISTRIBUTION IN FOUR NORTHEASTERN CITIES.

Merry, CJ., et al, Dec 1985, 50p, ADA-166 335, 12 refs

LaPotin, P.J. 40-3303

CONSTRUCTION MATERIALS, BUILDINGS POLAR REGIONS, MODELS, DISTRIBUTION. BUILDINGS,

POLAR REGIONS, MODELS, DISTRIBUTION. The Corps of Engineers conducted a field sampling program for inventorying building materials in the northeastern United States, and the data from the field program were compiled into a data base for statistical analysis. Correlation coefficients were derived between the independent variables and the surface area of the five building material types. The correlation coefficients were used in an optimal stepwise regression model developed for each material class for each city. A number of factors appear to be significantly associated with the distribution of building material exposure. However, the variables do not correlate at levels required for constructing adequate predictive models that would be applicable to other sampling locations.

SR 85-25 BLASTING AND BLAST EFFECTS IN COLD RE-GIONS. PART 1: AIR BLAST.

Mellor, M., Dec. 1985, 62p., ADA-166 315, 23 refs.

BLASTING, EXPLOSION EFFECTS, SHOCK WAVES, ATTENUATION, ANALYSIS (MATHEMATICS), POLAR REGIONS.

Air blast phenomena are reviewed and a digest of data is given, mainly in graphical form. To the extent possible, corresponding data are given for air blast in cold regions, provided that the prevailing conditions are significantly different from those of temperate regions.

USACRREL PRECISE THERMISTOR METER. Trachier, G.M., et al, Dec. 1985, 34p., ADA-166 470, 4 refs.

Morse, J S., Daly, S.F.

40-3305 FRAZIL ICE, WATER TEMPERATURE, THER-MISTORS, ICE FORMATION, MEASURING IN-

STRUMENTS, ACCURACY. STRUMENTS, ACCURACY.

To facilitate the study of frazil ice in the field, a highly accurate, portable water temperature meter was required. The USACRREL Precise Thermistor Meter was designed and built to meet this need. The meter is rugged, battery-operated, waterproof, and able to operate over a wide range of ambient temperatures. A unique feature of this instrument is the use of software to compensate for temperature-dependent variation in the analog electronics. The circuitry consists of an analog printed circuit board and a low power microcomputer. The resistance of a calibrated thermistor is determined and its temperature calculated using the Steinhart-Hart equation. The accuracy of the meter was determined both theoretically and in cold room tests. The hardware and software used in the meter are described.

SR 86-02 NITROGEN REMOVAL IN COLD REGIONS TRICKLING FILTER SYSTEMS.
Reed, S.C., et al., Fr. 1086, 39p., ADA-167 118. 19

refs

Diener, C.J., W y 40-3581

MENT. WATER TREATMENT. MICAL ANALYSIS. TEMPERA-WASTE T' SEEPAGL, MICAL ANALYSIS, TEMPERATURE EFFECTS, DESIGN, HEAT LOSS, POLAR REGIONS

Tricking filters are found in about 50° of the operating wastewater treatment systems owned by the U.S. Army, and more are likely for any new construction. Control of introgen, particularly ammonia in wastewater effluents is a growing necessity. Ammonia can be removed in tricking filters but the process is temperature-dependent

This study combined an intensive literature review with data collection at full-scale and pilot-scale systems. These results are presented and evaluated. A liquid temperature of at least 7 C is necessary in the filter bed for effective ammonia removal, and a separate single-purpose filter bed dedicated for intification is recommended when significant ammonia removal is required at cold regions locations. Criteria and equations are derived for future cold region system designs.

UNITED STATES—NEW HAMPSHIRE. This data report contains climatological measurements for the winters of 1980-81 and 1981-82 made at three sites in New Hampshire situated at elevations of 155 m, 870 and 1910 m above sea level Parameters measured included wind speed and direction, precipitation, temperature, humidity, and duration of icing events. Comparison of the data provides the opportunity to examine the influence of elevation on atmospheric icing occurrence and intensity. In New Hampshire, icing appears to occur only at elevations above about 900 m

PERFORMANCE OF HIGHWAY AND ALL-SEA-SON RADIAL TIRES AND TRACTION AIDS ON ICE AND IN SNOW.

Rogers, T, et al, Apr. 1986, 20p., ADA-168 872, 3 Liston, R A

43-4590

TIRES, PERFORMANCE, TRACTION, COLD WEATHER PERFORMANCE, COLD WEATHER

TES1S
This study compares the traction performance of a group of all-season radial tires, highway radial tires, link and cable chains. The tests were conducted on ice and snow. The all-season radials perform slightly better on ice, presumably because of the adhesive compound used in manufacturing these tires. The chains significantly improved traction on ice over bare tires, the link chain being best. In snow, the bare tires performed approximately the same. The cable chains provided only a slight improvement, while the link chains again performed best.

ICE BLASTING, PENETRATION TESTS, FLOAT-ING ICE, EXPLOSION EFFECTS, SUBGLACIAL OBSERVATIONS

OBSERVATIONS

Empirical prediction curves for ice blasting are given, and their derivation and use is explained. Alternative forms of the curves, which relate more closely to conventional underwater explosion technology, are developed and examined. Results of experiments with gas blasting devices are summarized and discussed in relation to the cratering effects of conventional explosives. There is a brief discussion of the energetics of ice fragmentation, effects of surface charges are outlined, and penetration by shaped charges is described. Son've test data that were not previously available are given in an appendix. in an appendix.

FROST HEAVE, AIRPORTS.

A laboratory study was conducted to determine the feasibility of stabilizing an organic sult for use in sub-base or base courses for all-weather, low-volume roads and artificlds in Alaska. The soil used in this study has an organic content of 12% and a modified Proctor value of 791 lb/cu ft at a 29% moisture content. The stabilizers evaluated were: cement, cement with additives (calcium chloride, hydrogen peroxide, sodium sulfate, and lime), lime, lime/fly sah, asphalt emulsion, tetrasodium polyphosphate, and calcium acrylate Unconfined compressive strengths obtained were 39 lb/sq in with 20% cement, 64 lb/sq in. with 20% cement and 2% calcium chloride, 51 lb/sq in. with 20% cement and 2% calcium chloride, 51 lb/sq in. with 20% cement and 1848 lb/sq in with calcium chloride. Lime and lime/fly sah proved to be ineffective for this soil. Although tetrasodium polyphosphate did not improve the soil's strength it did reduce frost susceptibility and permeability.

NAVIGATION, UNITED STATES—OHIO RIVER, UNITED STATES—PENNSYLVANIA—ALLEGHENY RIVER, UNITED STATES—MONON-GAHELA RIVER.

GAHELA RIVER.

Ice conditions on inland rivers can change rapidly and adversely affect navigation

The neemaps in this atlay were prepared to document the 1984-85 nee conditions on those reaches of the Ohio. Allegheny and Monongahela Rivers that are included in study areas for the River Ice management (RIM) Program, namely river mile 0 to 437 on the Ohio River, mile 0 to 7 on the Allegheny, and mile 0 to 65 on the Monongahela

The maps were prepared from interpretation of sertical aerial video imagery taken from a low-flying aircraft. The interpreted toe conditions were classified into 5 units and transferred to base maps by reference to navigation charts and topographic maps. Fragmented ice Cover and Ice Floes or Frazil Sluth and Pans were the most common ice units in the lower pools of the Monongahela River and lower Allegheny. Solid Ice Cover and Iragmented Ice Cover were the most common units in the upper pools of the Monongahela. Fragmented Ice Cover and Open Water were the most eximine units in

the Emsworth to New Cumberland pools of the Ohio; Open Water and Ice Floes or Frazil Slush and Pans were the predominant units in the downstream pools There were frequent cancellations of flights during the 1984-85 winter because of low cloud ceilings. To get more frequent video coverage of ice during the 1985-86 winter, a wider-angle lens on the video camera will be used. This will allow flights at a lower altitude, permitting video coverage even when the ceiling is low.

HEAT SINKS, TUNNELS, HEAT TRANSFER, ROCKS, THERMODYNAMICS, CONDENSATION, THERMAL CONDUCTIVITY, MATHEMATICAL MODELS, TEMPERATURE EF-FECTS. AIR MASSES.

FECTS, AIR MASSES.

This report examines the feasibility of condensing steam from an underground power source by heat conduction into the surrounding rocks. A mathematical model was utilized such that the condensing steam delivered a variable flux of energy to the walls of the condenser tunnel. Heat flow in the surrounding rock was limited to conduction A numerical analysis of the transient problem results in predictions of tunnel lengths and diameters needed to dissipate specified condenser heat loads as a function of initial steam pressure, surrounding rock thermal properties, and ambient rock temperature. The rock thermal conductivity exerts a large influence upon the required tunnel length, with tunnel length decreasing with increasing rock conductivity. The length decreasing with increasing rock conductivity. The quantitative predictions of the model indicate that a condensing steam tunnel in rock may be competitive with circulating water or ice/water heat dissipation modes

WINTER FIELD FORTIFICATIONS. Farrell, D., Aug. 1986, 50p., ADB-106 228, 23 refs

FORTIFICATIONS, MILITARY OPERATION, SNOW (CONSTRUCTION MATERIAL), WOODEN STRUCTURES, EMBANKMENTS, WINTER,

TESTS.

Preparation of winter field fortifications poses problems that are not encountered in any other environment. The primary construction materials available for aboveground construction are snow and wood. This report describes what snow is, and how and when to use it to the best advantage, and it presents the results of tests of the capacity of snow embankments to stop projectiles. The information presented is based on both laboratory and field test results. Both approaches were required to understand why a builet stops quickly in snow and how durable a snow fortification can be. Field tests showed that a non-fuzed round as large as that from the Soviet 145 mm KPV can be stopped by 2 m (66 ft) of packed snow Laboratory studies revealed the mechanics of buillet interaction with snow For the larger, fragmentation munitions field tests were cumberrevealed the mechanics of bullet interaction with snow For the larger, fragmentation munitions field tests were cumbersome and unproductive But a laboratory simulation of fragment penetration into snow showed that only 0.6 m (2.1) of packed snow stops the smaller, high-velocity fragments while 1.5 m (5.1) of snow is required to stop the larger, slower fragments To represent the larger, anti-armor, direct-fire weapons containing shaped-charge warheads, the 90-mm M67 and the 70-mm Soviet RPG-7 were used in field tests The results showed that 3 m (10.1) of snow absorted all effects, even after multiple impacts

WATER TEMPERATURE.

The thermal design of a horizontal ice heat sink with horizontal water flow is outlined using a computer model to give quantitative results. The mathematical model allows interaction between the ice sink and the surrounding rock material Data taken from an experiment, undertaken as part of this study, on melting, horizontal ice sheets were used in the mathematical model. Design curves are presented to estimate the outlet water temperature as a function of time and the rate of ice melt. The horizontal ice heat sinks can deliver outlet water at temperatures between 45 and 55 F for a considerable period of time (hundreds of hours) if the heat dissipation rate of the sink is less than 0.8 kW/ft. For this range of heat dissipation rates, the horizontal sink is comparable in performance to the vertical ice heat sink is remained in the mathematical model emphasizes the thermal superior of the heat sink with no consideration given to mechanical and plumbing problems construction techniques, or maintenance of the sink

SR 86-27 DRILL BITS FOR FROZEN FINE-GRAINED

ICE BLASTING, EQUIPMENT, ROTARY DRILL-ING, PERCUSSION DRILLING.

Navy underwater construction teams require a capability for making access holes through arctic sea icc.

Required hole diameters tange from less than 4 in. (100 mm) to more than 10 ft (3 m) in ice up to 15 ft (4.6 m) thick. Small diameter holes are to be completed in less than 4 hr and large diameter holes in less than 8 hr. The report first gives brief descriptions of the working environment, site access considerations, and probable operational procedure. Principles and techniques for penetrating sea ice are summarzed, with an initial list of 14 topics Twelve of these items are identified as potentially relevant, and are discussed more fully. They include 1) projectile penetration, 2) shaped charge penetration, 3) high pressure water jets, 4) blasting, 3) flame jets, 6) electrothermal devices, 7) hydrothermal devices, 8) rotary drilling, 9) percussive and vibratory penetration, 10) mechanical cutting, 11) chemical penetration, 12) exotic concepts. The final selection, which takes into account practical concerns and field experience, recommends the following things as basic tools a) small diameter auger drills (less than 4 in diam), b) large diameter auger drills (less than 4 in diam), b) large diameter auger drills (approx 9 in diam), c) chain saws, d) a hot water system for drilling and cutting. The discussion of associated equipment covers electric generators, hoists and lifting tackle, hand tools, and blasting supplies. Consideration is also given to single-fuel operation, bulk melting, and possibilities for use of compressed air Recommendations for development work by NCEL are given

SR 86-33

INSTRUCTIONS FOR COMPLETING A FIELD WORKSHEET FOR INVENTORYING BUILDING MATERIALS.

Merry, CJ, Dec. 1986, 25p., ADA-176 467, 9 refs.

CONSTRUCTION MATERIALS, PRECIPITA-TION (METEOROLOGY), ENVIRONMENTAL PROTECTION, DAMAGE CHEMICAL ANAL-YSIS.

A worksheet for use in the field was developed to inventory building materials in four northeastern cities in support of the EPA Acid Rain program. The initial form was tested for two of the cities, the redesigned and simplified form discussed in this report was used in the two remaining cities. The worksheet was designed to provide information on the census tract, land use type and sampling frame, the dimensions and type of building, the lot size, the materials distribution percentages in the foundation, first story and all above stories, and the surface area and material types for the roof roof-mounted apparatus (sents, flues, stacks, skylights and flashing), chimneys, rain gutters, downspouts and fences. The worksheet is recommended for future surveys of building materials in other cities. A worksheet for use in the field was developed to inventory

CALIBRATING HEC-2 IN A SHALLOW, ICE-COVERED RIVER.

Calkins, D J, et al. Dec 1986, 25 refs., ADA-176 485, 7 refs

Adley, M D. 41-2531

FLOOD CONTROL, ICEBOUND RIVERS, ICE COVER THICKNESS, RIVER FLOW, WATER LEVEL, MATHEMATICAL MODELS, FLOAT-ING ICE, FREEZEUP, ICE COVER EFFECT.

HEC-2 has recently been modified to accept input for a floating ice cover several techniques were evaluated in a steep, shallow river. The ice cover thickness, as expected. was the dominant parameter affecting the water levels and not the Manning's roughness coefficient of the ice cover Excellent field data on ice cover thicknesses, water levels and flow discharges were available for calibration. The relatively shallow depths of less than 6 ft and ice covers of up to 3-ft thick created special problems in matching the water levels. The actual ice cover thicknesses measured in the field should be used as a guide for ice thickness input to the model for shallow streams. The transition of ice cover thickness from one section to the next in the model is extremely critical, otherwise there will be excessive head losses. Several methods for interpolating the ice thickness between the measured sections were attempted in trying to simulate the freeze-up, and ineffective flow areas were blocked off as well. The latter provided the most realistic simulation of flow velocities beneath the ice cover.

Brockett, B.E.

AUGERS, FROZEN GROUND STRENGTH, DRILLS, MILITARY ENGINEERING, PENE-TRATION TESTS, BOREHOLES.

TRATION TESTS, BOREHOLES.

Auger bits 65 in. (165 mm) and 95 in (241 mm) in diameter were modified to satisfy military and general engineering requirements for producing holes in frozen soil. A commercial bit was selected since it appeared to need only minor modification. Penetration tests were run in frozen.

The region of soils one type containing some gravel. Modifiminor modification Penetration tests were run in frozen fine-grained soils, one type containing some gravel Modifications, which primarily involve changes in cutter relief angles, substantially improved performance Penetration rates were as high as 5 ft/min (15 m/min), compared to 0-14 ft/min (0-0.4 m/min) for the unmodified bits

DEVELOPMENT OF A FRAZIL ICE SAMPLER. Brockett, B.E., et al, Dec. 1986, 12p, ADA-179 043 Sellmann, P.V.

FRAZIL ICE, CORE SAMPLERS, ICE SAMPLING, DESIGN, GRAIN SIZE

A lightweight sampler has been constructed to provide large A lightweight sampler has been constructed to provide large cores from frazil ice deposits. Samples containing frazil ice particles ranging in size from 1 mm to over 70 mm, including the interstitial water, were successfully recovered during field tests. These samples were nearly undistrubed while confined in the sample tube, based on a comparison with samples acquired using a freeze probe technique.

SR 86-38 LOW TEMPERATURE EFFECTS ON SORP-TION, HYDROLYSIS AND PHOTOLYSIS OF ORGANOPHOSPHONATES—A LITERATURE REVIEW

Britton, K.B., Dec. 1986, 47 refs., ADA-178 349, Refs. p.42-47 41-3050

POLLUTION, CHEMICAL ANALYSIS, ICE COMPOSITION, SNOW COMPOSITION, SOIL COMPOSITION, FROZEN GROUND, TEMPER-POLLUTION, ATURE EFFECTS, ENVIRONMENTAL IMPACT.

A survey was made of the open literature to determine the information available on the persistence of organophos-phonate chemical agents in the environment. This review phonate chemical agents in the environment. This review focuses on low temperature hydrolytic and photolytic Jegradation of the nerve agents GA (Tabun), GB (Sarin), GD (Soman) and VX. The role of adsorption to ice, snow and frozen soils and sediments is also discussed in relation to these degradative processes. Suggestions are made for the investigation of agent decomposition using simularity. The method proposed for the study of agent persistence is based on the use of linear free energy relationships, which should allow for more reliable prediction of agent behavior than if a single simulant is used as a model compound SR 86-39

COMPARATIVE TRACTIVE PERFORMANCE OF MICROSIPED AND CONVENTIONAL RADIAL TIRE DESIGNS.

Blaisdell, G.L., et al, Dec. 1986, 11p., ADA-178 355, 4 refs

Morrison, T.L.

TIRES, TRACTION, RUBBER ICE FRICTION, BRAKES (MOTION ARRESTERS), DESIGN.

The braking and driving tractive effectiveness of aftermarket The braking and driving tractive effectiveness of aftermarket microsping of all-season design radial tries was studied as an alternative to standard traction aids such as snow tires, studs, and chains Microsping is a process that involves laterally slicing the tires to a depth close to that of the tread depth, thus dividing each tread element into several adjacent, contacting elements Microsping removes virtually no material from the tire. From previous studies, it is known that traction on ice is overwhelmingly dependent on the adhesion between the ice surface and the tire tread compound. Since microsping does not alter the compound, a measurable improvement in traction on ice for several tire types and temperatures, as expected, was not found

WATER POLLUTION, SOLUTIONS.

A number of 0 45-micron disposable filters were tested for sorption of HMX, RDX, TNB, DNB, tetryl, TNT and 2,4-DNT.

Both aqueous and mixed aqueous-organic solvent matrices were tested. For aqueous matrices, the Nalgene (green) cellulose acetate filter sorbed significant amounts of HMX, RDX, TNT and 2,4-DNT. The Gelman Acro LC25 filter, described as a naturally hydrophilic fluoropolymer, also sorbed significant levels of HMX, TNT and tetryl Where sorption was found, losses were greatest for the first portion of filtrate passed through the filter and for filtration conducted slowly Addition of 50% organic solvent prior to filtration eliminated sorption problems for all filters tested When aqueous matrices are filtered, the recommended procedure is to discard the first 10-mL portion of filtrate and retain the second 10-mL portion for analysis

EXTINCTION COEFFICIENT MEASUREMENT IN FALLING SNOW WITH A FORWARD SCAT-TER METER.

Koh, G., Mar. 1987, 9p., ADA-180 958, 5 refs. 41-3849

LIGHT SCATTERING, SNOWFALL, INFRARED RADIATION, LIGHT TRANSMISSION, FOG, MILITARY OPERATION.

A forward scatter meter designed to measure the visible extinction coefficients measured with a forward scatter meter and a transmissometer indicates that a forward scatter meter can be used to measure extinction coefficient in falling snow. The different calibrations required for snow and fog are partially explained by examining the effect of particle size on the angular distribution of scattered light.

TREATMENT AND DISPOSAL OF ALUM AND OTHER METALLIC HYDROXIDE SLUDGES Reed, S.C., et al, Mar. 1987, 40p. + plates, ADA-180 960, 19 refs

This report describes a procedure for measuring R-values on actual buil lings, using thermography, heat flux transducers,

and data acquisition equipment. R-values measurement is necessary to optimize investment in additional insulation and permits confirmation of the quality of newly installed insulation.

PREPARATION AND DESCRIPTION OF A RE-SEARCH GEOPHYSICAL BOREHOLE SITE CONTAINING MASSIVE GROUND ICE NEAR FAIRBANKS, ALASKA.

Delaney, A.J., June 1987, 15p., ADA-183 186, 4 refs. 41-3627

PERMAFROST PHYSICS, GROUND ICE, BORE-HOLES, GEOPHYSICAL SURVEYS, SOIL TEM-PERATURE, UNITED STATES—ALASKA— FAIRBANKS.

FAIRBANKS.

A geophysica control site consisting of 27 holes drilled in permafrost and cased with ABS pipe has been completed near the USACRREL permafrost tunnel at Fox, Alaska The site provides excellent control on a range of material types in permafrost terrain including frozen silt, gravel, bedrock, and all common ground-ice types such as wedge, lens, and pore ice. The holes delineate massive groundice features of which there is no surface manifestation fround temperature data is available from a small-diameter glycol-filled hole. This report describes the site, its preparation, and the soil logs and data obtained.

TRACKING TWO-DIMENSIONAL FREEZING FRONT MOVEMENT USING THE COMPLEX VARIABLE BOUNDARY ELEMENT METHOD. Hromadka, T.V., II, June 1987, 58p., ADA-183 547,

COMPUTER PROGRAMS, FROZEN GROUND TEMPERATURE, SOIL FREEZING, SOIL WATER MIGRATION, PHASE TRANSFORMATIONS, BOUNDARY LAYER, THERMAI LAYER, THERMAL REGIME, HEAT FLUX.

TIONS, BOUNDARY LAYER, THERMAL REGIME, HEAT FLUX.

The Complex Variable Boundary Element Method (CVBEM) is used to develop a computer model for estimating the location of the freezing front in soil-water phase change problems. This computer program, CVBFRI, is based on the following major assumptions: 1) the problem is two-dimensional, 2) the entire soil system is homogeneous and soitopic, 3) the problem thermal boundary conditions are constant values of temperature for stream function), 4) soil-water flow effects are neglected (the problem is strictly geothermal), 5) all heat flow from the freezing front is within the control volume, there is no heat flux associated with the freezing front from exterior of the control volume, and 6) the freezing front movement is slow enough that heat flux along the moving boundary can be determined by assuming steady state heat flow conditions for small durations of time (i.e., timesteps). The CVBEM is used to model the thermal regime of the voil system. The theory and development of the CVBEM are given in CRREL Internal Report 969. Complex Variable Boundary Elements. Engineering, by Hromadka. Because the numerical technique is a boundary integral approach, the control volume thermal regime is modeled with respect to the boundary values, and, therefore, the CvBERI data entry requirements are significantly less than those usually required of domain methods such as finite-differences or finite-elements. Soil-water phase change along the freezing front is modeled as a simple balance between computed heat flux and the evolution of soil-water volumetric latent heat of fusion. To model the displacement of the freezing front program CVBFRI front doordinates with respect to a vector normal to the freezing front coordinates with respect to a vector normal to the freezing front to ordinates with respect to a vector normal to the freezing front boundary.

NODAL DOMAIN INTEGRATION MODEL OF TWO-DIMENSIONAL HEAT AND SOIL-WATER FLOW COUPLED BY SOIL-WATER PHASE CHANGE. Hromadka, T.V., II, June 1987, 124p, ADA-183 518,

FROZEN GROUND THERMODYNAMICS, SOIL FROZEN GROUND INERMODINAMICS, SOIL
WATER MIGRATION, HEAT TRANSFER,
FREEZE THAW CYCLES, HEAT FLUX, PHASE
TRANSFORMATIONS, MATHEMATICAL
MODELS, COMPLTER APPLICATIONS, TEMPERATURE EFFECTS, SNOW COVER EFFECT A model of phase change in freezing and thawing soils is developed for cold regions engineering problems which require two-dimensional analysis of the thermal regime of soils. These problems include complex boundary conditions soils These problems include complex boundary conditions such as atmosphere ground surface thermal interaction and snowpack insulation. Other concerns include complex soil conditions such as the presence of a peary muskeg or fundralises oil which may preside thermal insulation for understuce tich interal soil. Although several models have been developed to predict temperatures in feezing and thawing soils, often the key question is simply without or not the soil is friezin since soil structural properties are ugnificantly influenced by the soil water state of phase. In this report, a simple two dimensional model is developed for use in soil regions engineering studies. A FORTRAN compiler program is available, which as composition to the conditional control of the soil was available, which as composition to the conditional control of the control of t coal regions engineering studies. A FORTRAN computer program is available which accommodates two-dimensional

heat and soil-water flow models as coupled by an isothermal phase change model. The program can be used to analyze two-dimensional freezing-thawing problems which have sufficient known information to supply the necessary modeling parameters, boundary conditions, and initial conditions.

FREEZE-THAW TEST TO DETERMINE THE FROST SUSCEPTIBILITY OF SOILS.
Chamberlain, E.J., Jan. 1987, 90p., ADA-180 000, 7

refs

FREEZE THAW TESTS, PAVEMENTS, FROST HEAVE, FROST RESISTANCE, AIRPORTS, SOIL FREEZING, THAW WEAKENING, AIRCRAFT LANDING AREAS.

LANDING AREAS.

A new freezing test for determining the frost susceptibility of soils is presented to supplant the standard CRREL freezing test currently specified by the Corps of Engineers. This test reduces the time required to determine the frost susceptibility of a soil in half. It also allows for the determination of both the frost heave and thaw weakening susceptibilities and considers the effects of freeze-thaw cycling. The new freezing test eliminates much of the variability in test results caused by the human element by completely automating the temperature control and data observations.

BENCHMARK DESIGN AND INSTALLATION: A SYNTHESIS OF EXISTING INFORMATION. Gatto, L.W., July 1987, 73p., ADA-183 925, 27 refs. 42.92

BENCH MARKS, COLD WEATHER CONSTRUCTION, FROST HEAVE, STABILITY, SUBSIDENCE, DESIGN, SURVEYS.

DENCE, DESIGN, SURVEYS.

Techniques used for topographic, hydrographic, construction, boundary, geodetic and structural movement surveys are only as accurate as the benchmarks used as reference. In northern areas, frost action can cause substantial vertical movement of benchmarks. Benchmarks may also subside or shift in wetlands and coastal areas. Various benchmark designs and installation procedures reduce or eliminate movement, but information on the designs and procedures is widely scattered and not available to Corps of Engineers Districts in one report. This report is a synthesis of information compiled from surveys of Corps of Engineers Districts and Divisions, U.S. and Canadian government agencies, private industry and a literature review. Matrices for selecting and installing benchmarks that meet third-order accuracy requirements or better and that are appropriate for various climatic and soil conditions were prepared from the synthesized information.

Procedures to be followed. he synthesized information. Procedures to be followed while installing various types of benchmarks are included Procedures to be followed

EMBANKMENT DAMS ON PERMAFROST: DE-SIGN AND PERFORMANCE SUMMARY, BIB-LIOGRAPHY AND AN ANNOTATED BIBLIOG-

Sayles, F.H., July 1987, 109p, ADA-184 163, Refs p.28-102.

PERMAFROST BENEATH STRUCTURES, DAMS, EMBANKMENTS. SEEPAGE, COLD WEATHER CONSTRUCTION, DESIGN, DEFOR-MATION, PONDS, SPILLWAYS, FREEZE THAW CYCLES.

The designs of embankinent dams on permafrost can be divided into two general types, frozen and thawed. The frozen type of embankinents and their foundations are maintained frozen during the life of the structure. The thawed type of embankinents usually are designed assuming that the embankment will remain unfrozen and its permafrost foundation will thaw during construction or during the operation of the structure. In some locations where water is to be retained intermittently for short periods of time, thaved embankments have been designed assuming the permafrost will remain frozen throughout the life of the embankment in selecting this type of design for a particular site, many factors that are peculiar to cold regions must be considered. This summary of methods of design, construction and operation of embankment dams in permafrost areas records the successes and some failures that have occurred. The designs of embankment dams on permafrost can be and some failures that have occurred. Embankment dams have been built and successfully operated in Canada, Greenland, the USSR and Alaska. A number of failures have been reported in the USSR and one in Alaska. Most of the difficulties arose because insufficient attention was given to establishing and maintaining a reliable frozen condition and to controlling seepage.

THICKNESS.

This paper reports on the response of a floating saline ice sheet to penetration and perforation by 25.4-mm-diameter projectiles with 3 nose shapes a full cone, a truncated cone and a full flat. Impact velocity was varied to produce behavior ranging from slight penetration to complete perforation of the 210- to 280-mm-thick ice sheet. The extent of crushing and fracturing adjacent to the path of the projectile was quantified, indicating the existence of a zone of crushing extending 1 to 2 body diameters into the ice sheet from the cavity wall. A series of shots into free-floating targets indicated that for penetrations of roughly two-thirds of the sheet thickness, the depth of penetration did not vary significantly as the target size was reduced to 24 body diameters. Texts on coated projectiles indicated that no significant abrassion occurred between the ice and the nose area of the projectile information is also presented on the effects of gun pressure, nose shape, average sheet temperature and angle of attack on the depth of penetration.

SORPTION OF CHEMICAL AGENTS AND SIMULANTS: MEASUREMENT AND ESTIMA-TION OF OCTANOL-WATER PARTITION CO-

Leggett, D.C., Sep. 1987, 15p , ADB-117 069, 14 refs. 42-1790

MILITARY OPERATION, CHEMICAL COMPO-SITION, SOIL POLLUTION, WATER FLOW, SOLUBILITY, TIME FACTOR, COUNTERMEAS-URES, ANALYSIS (MATHEMATICS), POLAR REGIONS.

Octanol-water partition coefficients were determined experimentally for 8 simulants. These were supplemented with published fragment constants and water solubilities to predict log K(ow) values of several threat agents. These estimates can be used to predict sorption and transport in soils. If correct, organophosphorus agents are more mobile in soil water than previously expected.

METALS.

The response to short-pulse radar of land mines emplaced in snow was observed throughout the winter of 1985-86 in Fairbanks, Alaska. The radar produced a pulse of a few nanoseconds duration with a spectrum centered near 900 MHz, resistively loaded dipole antennas were used at two polarizations. The mines—standard anti-armor types and a Plexiglas simulation of one of these—were emplaced at various orientations on or above a cleared ground surface and monitored. There was little change in the mine responses that occur before the ground surface response under conditions of 0 and 35 cm of snow, the maximum depth achieved, as long as the snow was dry. Responses from the migrating freeze-thaw interface in the active layer masked some of the later mine responses. The radar effected no response from several of the mines when the pack began to thaw and temperature was nearly constant at 0 C. Some polarization sensitivity was always evident, depending on the orientation of the mine. In no case was there any response to the Plexiglas simulation. UHF short-justeradar is an excellent mine detection technique in dry snow so long as mines are metallic, but is unsuitable for detecting small, plastic mines in snow.

CRITICAL COMPARISON OF MOVING AVER-AGE AND CUMULATIVE SUMMATION CONTROL CHARTS FOR TRACE ANALYSIS DATA. McGcc, LE., et al., Nov. 1987, 57p., ADA-188 312, 20

Grant, C.L.

WASTE DISPOSAL, CHEMICAL ANALYSIS, EN-VIRONMENTAL IMPACT, SOIL POLLUTION, ISOTOPE LABELING, DETECTION

Percentage recovery estimates have been obtained for 15 analytes or surrogates of environmental concern by four

commercial laboratories over a two-year period. These quality control analyses were performed using standardized methods on a control soil matrix. Over 100 lots of results were available for many of these analytes. This massive amount of data afforded an opportunity to compare the sensitivity of different quality control protocols for detecting "out-of-control" situations and also to compare the performance of the four laboratories. Recovenes averaged 90-100% for 11 of 15 analytes. Reproductibility of recovery estimates was surprisingly consistent from lab-to-lab. From a comparison of moving average control charts (n=2 and n=3) with cumulative summation charts, the n=3 moving average charts were considered most suitable for routine lot-to-lot control by contractors. The cumulative summation charts are very useful for situations requiring critical diagnostic analysis of problems. Where duplicate recoveries were obtained with each lot, lot-to-lot variability was similar in magnitude to within-lot variability. To avoid an excessive number of out-of-control responses, control limits should be based on total variability rather than within-lot variability.

SR 87-22 COMPARISON OF METHANOL AND TETRA-GLYME AS EXTRACTION SOLVENTS FOR DETERMINATION OF VOLATILE ORGANICS IN SOIL

Jenkins, T.F., et al, Nov 1987, 26p., ADA-189 028, 23 refs

Schumacher, P.W.

SOIL CHEMISTRY, WASTE DISPOSAL, WATER POLLUTION, DETECTION, SOLUBILITY.

POLLUTION, DETECTION, SOLUBILITY.

The abilities of methanol and tetraglyme to extract chloroform, benzene, toluene, and tetrachloroethylene from vapor-contaminated soils are directly compared. Comparisons are made both with respect to process kinetics and analyte recovery using an extraction procedure based on equilibration on a wrist-action shaker and determination using a purge-and-trap GC/MS. An equilibration period of 10 minutes is recommended for extraction using either methanol or tetraglyme. In all cases methanol was as good as or better than tetraglyme with respect to analyte recovery. This was even the case for soils contaminated with an oily residue. While commercial methanol and tetraglyme both contain measurable levels of volatile atomatics, simple rotary evaporation was successful in removing these contaminants to levels below detection limits for tetraglyme. Thus, for cases where very small amounts of these contaminants must be detected, degassed tegraglyme would be superior. Overall, however, methanol is considered the best choice for extraction of volatile organics where subsequent analysis is to be conducted by purge-and-trap GC/MS.

ICE STRENGTH, FROZEN GROUND
STRENGTH MEASURING INSTRUMENTS, ICE
CRYSTAL STRUCTURE, LOW TEMPERATURE
TESTS, BRITTLENESS, DYNAMIC LOADS,
CONSTRUCTION MATERIALS, IMPACT STRENGTH.

Most materials at low temperatures change their modulus and tend to become brittle. When using these materials in stria ural components that are likely to be subjected to impact it is important to understand their behavior at low temperatures under dynamic loading. The CRREL split Hopkinson Test Bar was designed and set up to conduct compressive strain rate tests (up to 1000 strains/s, i.e., in, infores) at low temperatures (down to -100 C). The results provide dynamic stress-strain, relationships of materials at low temperatures by considering the transmission of the stress wave through a test specimen is contained in a liquidition of the stress wave through a test specimen is contained in a liquidition of the stress wave through a stress wave through a stress wave and clastic striker impacts the bar as a result a stress wave passes down the bar. At the specimen a part of the wave is reflected and the rest is transmitted to the second bar. Strain gauges mounted on the bars record the wave hapes, which are analyzed to obtain the dynamic stress-strain relationships. The test bars are 1-1.2 in, in diameter and each is 3 ft long. The apparatus is suitable for testing light metals, plastics, composites, rocks, i.e., and frozen soil. The data acquisition and analysis system are completely automatic, using software developed at CRREL, so the system provides for a tapid and low-cost method for high strain, atc. Most materials at low temperatures change their modulus

ANALYTICAL METHOD FOR DETERMINING TETRAZANE IN WATER.

Walsh, M.E., et al, Dec. 1987, 34p., ADA-189 045, 15 refs.

Jenkins, T.F.

EXPLOSIVES, GROUND WATER, MILITARY OPERATION, CHEMICAL ANALYSIS, WATER POLLUTION

POLLUTION.

An ion-pairing RP-HPLC method was developed to determine tetrazene in water. The method uses an LC-18 column and a mobile phase of 2/3 v/v methanol-water modified by 0.01 molar 1-decenesulfonic acid sodium salt. The mobile phase pH was adjusted to 3 with glacial acctic acid. The modified mobile phase was optimal for separating of tetrazene from potential interferences by other explosive compounds such as HMX and RDX and for allowing elution of TNT within a 15-minuter run time. The retention time for tetrazene was 2.8 minutes

The UV detector was an access 2.80 nm. A linear model with zero intercept was for tetrazene was 2.8 minutes The UV detector was set at 280 nm A linear model with zero intercept was found to adequately describe the calibration data. The concentration range tested was 6.2-1238 microgram/L. A spike recovery test on each of 4 days gave an average recovery of 103%. A reporting limit of 7.25 microgram/L was estimated The relative standard deviation was approximately 2% over the range tested Tetrazene was found to be unstable in an aqueous medium at room temperature Concentrations decreased by 96-100% over 24 hours. Chilled solutions were less prone to degradation than room temperature solutions, and heated solutions (50 C) degraded completely within two hours.

SR 87-28 XYFREZ.4 USER'S MANUAL.

HEAT TRANSFER, COMPUTER PROGRAMS, PHASE TRANSFORMATIONS, MATHEMATICAL MODELS, LATENT HEAT, HEAT CAPACITY, TEMPERATURE DISTRIBUTION.

TY, TEMPERATURE DISTRIBUTION.

Using the program XYFREZ, version 4, one may simulate two-dimensional conduction of heat, with or without phase change. The mathematical method employed uses finite elements in space and finite differences in time, and includes latent heat effects through a singulanty in the heat capacity. The user need have no real familiarity with either the underlying equations or the numerical procedures. He must only specify material properties, geometrical features, initial and boundary conditions, and information on the desired manner and duration of simulation through time. Heterogeneous material properties may be specified Boundary conditions currently implemented allow one to specify 1) temperature values which vary arbitrarily in space and time, 2) convective conditions, via a heat transfer coefficient and an ambient temperature, and 3) a no-flux or symmetry condition. The program outputs computed temperature values at numerical mesh points, as well as information for later plotting. From the latter one may see the mesh configuration as well as the phase change isotherm location on it over time.

ICE CONDITIONS ALONG THE OHIO RIVER AS OBSERVED ON LANDSAT IMAGES, 1972-

Gatto, L.W., Jan. 1988, 162p, ADA-191 172, 25 refs. 42-3010

ICE CONDITIONS, RIVER ICE, REMOTE SENS-ING, ICE NAVIGATION, AERIAL SURVEYS, LANDSAT, PHOTOINTERPRETATION, SEA-SONAL VARIATIONS, UNITED STATES—OHIO RIVER.

RIVER.

Landsat images were used to map ice distributions along the Ohio River—lee conditions were inferred based on image grey tones interpreted using conventional photointerpretation techniques—Portions of the river that appeared black were considered ince-free—Grey tones were interpreted as ice that varied from patches of thin, snow-free solid or fragmented ice, sonetimes with open areas, to floes, pans and slush—A white tone represented thick see or snow-covered lice with few interspersed open areas—lee that produced grey tones on the images occurred most frequently.

Lee typically forms in late Dec. or early Jan—on the Ohio River and is gone by mid to late Feb—lee was observed on the upstream section of the river from 1972 to 1985, on the middle section from Greenup Dam during 7 of the 13 winters from 1972 to 1985, on the middle section from Greenup Stream section from Cannelton Dam to the Mississippi River during 4 winters—The most severe and long-lasting ice conditions—ccutred during the 1976-77 winter when accorded 65% of the upstream section, 56% of the middle section, and 78% of the downstream section

PREDICTING PRODUCT WATER QUALITY FROM THE 600-GALLON-PER-HOUR RE-VERSE OSMOSIS WATER PURIFICATION UNIT. FIELD WATER SUPPLY ON THE WIN-TER BATTLEFIELD.

Bouzoun, J.R., Feb. 1988, 7p., ADA-194 988, 4 refs.

WATER SUPPLY, MILITARY ENGINEERING, MILITARY RESEARCH, LOGISTICS, WATER TREATMENT, WATER CHEMISTRY, ANAL-YSIS (MATHEMATICS).

A prelimmary equation for predicting the total dissolved solids (TDS) concentration in the product water from the 600-gph ROWPU is presented the raw water temperature and TDS concentration as input data. Both of these variables can be easily measured in the field. The equation is presently limited to raw water TDS concentrations in the range of 800-900 mg/L. As data become available for a greater range of raw water TDS concentrations, including seawater, the equation will be modified The standard error of the estimate is 3.4 mg/L.

PRELIMINARY DEVELOPMENT OF A FIBER OPTIC SENSOR FOR TNT.

Zhang, Y., et al, Mar. 1988, 16p., ADA-191 865, 6

Seitz, W.R., Sundberg, D.C., Grant, C.L. 42-2809

SOIL POLLUTION, DETECTION, GROUND WA-TER, OPTICAL PROPERTIES, MILITARY RE-SEARCH, WATER POLLUTION.

Research aimed at the development of a fiber-optic based sensor is described for *in-situ* detection of TNT in groundwater. Three approaches were evaluated in depth. All three involved use of a material to concentrate TNT in the field of view of an optical fiber. The materials tested were 1) a concentrated dextran solution isolated by a semi-permeable membrane, 2) a pre-swollen cross-linked polysumly alcohol polymer; and 3) an amine-loaded PVC membrane. Another approach based on the formation of a colored TNT anion at high pH was also considered. The amine-loaded PVC membrane appears to have the most promise. Clear membranes were prepared which reacted with TNT to form a colored product. Measurement is made at 520 nm which is very convenient for fiber optic-based sensing. Various primary amines were assessed Research aimed at the development of a fiber-optic based ous primary amines were assessed

DEVELOPMENT OF THE UNSURFACED ROADS RATING METHODOLOGY. Eaton, R.A., Apr. 1988, 13p., ADA-195 837, 2 refs.

ROAD MAINTENANCE, SURFACE PROPER-TIES, SURFACE DRAINAGE, ENGINEERING.

TIES, SURFACE DRAINAGE, ENGINEERING. A method for rating the surface drainage and conditions of unpawed roads has been developed, and a field manual has been prepared to assist county, municipal, military and township highway agencies in managing the maintenance of such roads. The types of distress found in unpawed roads are categorized and listed in the manual. For each type of distress listed, there is a description of the distress and the levels of severity, an illustration, and a measurement method. The manual also includes instructions on how to inspect unsurfaced road conditions, a field inspection work sheet, and a family of deduct value curves for the distress types and associated severity levels. The curves were validated using data gathered during 7 field surveys throughout the United States. This report describes the development of the deduct value curves for the 7 distresses identified in unsurfaced road maintenance. The development of the original curves and the adjustments after each ment of the original curves and the adjustments after each field trip are described. The surface and drainage rating method and maintenance management strategies can be used. alone, or they can be adapted for use with any existing computerized pasement management system (PMS). The rating method and strategies are compatible with the PAVER PMS developed by the U.S. Army Corps of Engineers and the American Public

ICE CONDITIONS ALONG THE ALLEGHENY AND MONONGAHELA RIVERS AS OBSERVED ON LANDSAT IMAGES, 1972-1985.

Gatto, L.W., May 1988, 106p, ADA-196 432, 11 refs

RIVER ICE, ICE CONDITIONS, REMOTE SEN ING, ICE NAVIGATION, LANDSAT, SNOW COVER EFFECT, AERIAL SURVEYS, PHOTOGRAPHY, UNITED STATES—ALLEGHENY RIVER, UNITED STATES—MONONGAHELA RIV-FR

ER.

Landsat images were used to map ice distributions along a 72-mile section of the Allegheny River, and the 129-mile-long Monongahela River. River reaches with greyice and white ice were mapped based on image tones using conventional photointerpretation techniques. Portions of a river that appeared black were mapped as ice free, although thin, transparent ice could also appear black. Grey tones were produced by ice that varied from patches of solid or fragmented ice with large open-water areas, to floes, pans, slush, or thin ice mixed with open areas. A white tone was produced by thick ice or snow-covered ice with very small or no open areas. Ice that produced grey tones was more frequent than ice that produced a white tone. Ice was observed on the Allegheny River during 10 of the 13 winters from 1972 to 1985, with the most severe ice conditions in 1976-77 when 100% of the river was covered with white ice. The Monongahela River had ice during 7 winters. Grey ice and white ice were observed covering the entire Monongahela River during the 1983-84 winter. During 1976-77, grey and white ice covered 94%

INVENTORY OF ICE PROBLEM SITES AND REMEDIAL ICE CONTROL STRUCTURES. Perham, R.E., July 1988, 9p., ADA-197 967, 12 refs.

RIVER ICE, ICE CONTROL, ICE NAVIGATION, ICE CONDITIONS, STRUCTURES.
As part of the River Ice Management (RIM) program, several

As part of the River Ice Management (RIM) program, several ice-affected, navigable rivers were studied to find locations where ice problems occur on a regular basis. The rivers studied were the Illinois River and the Ohio River and its tributance, especially the Allegheny and the Monongahela Several problem areas were found at river bends, islands, and locks and dams and were generally caused by having too much broken ice in the ship track. One site had a serous frazil ice problem. Ice control structures such as ice booms and deflector booms were investigated for use at certain locations. The report includes a list of 64 ice problem sites, 5 locks and dams that could benefit from ice control structures, and 3 proven structures that are technically applicable.

EVALUATION OF SEVERAL AUGER BITS IN FROZEN FINE-GRAINED SOILS, ASPHALT, AND CONCRETE.

Sellmann, P.V., et al, July 1988, 10p., ADA-199 415, 3 refs.

Brockett, B.E.

AJUGERS, FROZEN GROUND STRENGTH, DRILLING, CONCRETE STRENGTH, BITU-MENS, GRAIN SIZE, TESTS.

MENS, GRAIN SIZE, TESTS.

Several auger bits were evaluated for drilling in frozen ground, asphalt, and concrete to determine bit performance in a wide range of materials. Promising bits in the 9- to 10- in (229- to 254-mm) diameter range were used with varying success depending on bit configuration. Bits included finger bits and a two-wing bit with continuous cutters It was possible to penetrate all the test materials, with performance depending on bit parameters and characteristics of the drill rig. Drill rig specifications are important because of the high torque and vertical thrust required for drilling in these hard materials. The finger bits have an advantage over bits with fixed cutters (voldered to the bit) for this demanding drilling, since damaged and duit cutters can be rapidly replaced in the field without special equipment. Several smaller-diameter bits 35 in (89 mm) were also tested in frozen ground equipment. Several smaller-diameter bits 3.9 in the minute to 6.5 in (165 mm) were also tested in frozen ground only.

PREDICTION OF OCTANOL-WATER PARTI-TION COEFFICIENTS OF ORGANOPHOS-PHONATES: EVALUATION OF STRUCTURE-UNCTION RELATIONSHIPS.

Britton, K B, et al, Aug. 1988, 24p., ADB-126 287, 44 refs.

Grant, C.L.

MILITARY RESEARCH, CHEMICAL COMPOSITION, MOLECULAR STRUCTURE, FROZEN GROUND, SNOW COMPOSITION, ENVIRONMENTAL IMPACT, ANALYSIS (MATHEMATICAL CONTROL OF THE PROPERTY OF THE PRO

Three theoretical approaches were evaluated for the prediction of octanol-water partition coefficients for organophosphonates Three theoretical approaches were evaluated for the prediction of octanol-water partition coefficients for organophosphonates. The first involved the development of a series of substituent constants based on experimentally determined partition coefficients. A linear relationship was found between the log of the partition coefficient (log P) and substituent constants, indicating possible utility for predicting partitioning behavior for chemical agents. This approach is limited by the available data for some important substituents. The second approach investigated involves discetting molecules into a series of structural elements called fragments. Log P is calculated by summing the corresponding fragment values. Octanol-water partition coefficients calculated for organophosphorus compounds disagreed significantly with experimentally determined values. Molecular connectivity was the third method evaluated. Values obtained by this method are not derived from experimental data but are solely based on molecular structure. Connectivity indices are based on the number and types of atoms and bonds with the molecule. The most promising results were obtained using compounds that are structurally similar to chemical agents containing only aliphatic substituents. Agreement between experimental and predicted values was highly variable. It appears that molecular connectivity cannot at present be used to accurately predict K(ow) values for chemical agents. Overall, the use of structure-function relationships is not recommended for the accurate prediction of chemical agent partitioning at their current stage of development.

ICE CONTROL IN RIVER HARBORS AND FLEETING AREAS.

Perham, R E., Aug. 1988, 7p, ADA-199 369, 9 refs

ICE CONTROL, RIVER ICE, ICE NAVIGATION. PORTS, ICE REMOVAL, CHANNELS (WATER-

WAYS)

Lee control in river harbors and fleeting areas in the northern tier of the United States east of the Mississippi River is handled mainly by the barge and towboat companies. Fleeting area portection in many locations is provided by its provided by the possible, unused barges are anchored in side channels and below islands or set along one side of the waterway in large groups for ice protection. Incetreaking is done by towboats, without barges, and a wide track is broken out. Alternative methods of ice control are discussed.

HARD-SURFACE RUNWAYS IN ANTARCTICA. Mellor, M., Aug. 1988, 87p., ADA-200 444

RUNWAYS, AIRCRAFT LANDING AREAS, ICE RUNWAYS, SNOW ROADS, PAVEMENTS, TRAFFICABILITY, AIRPLANES, FREEZE THAW CYCLES, COST ANALYSIS, ANTARCTICA MCMURDO STATION, ANTARCTICA AMUNDSEN SCOTT STATION

AMUNDSEN SCOTI STATION.

The feasibility of constructing and maintaining hard surface snow runways at McMurdo Sound and South Pole was studied. Lasting technology was reviewed, and proposals for novel techniques and machines were put forward. It was concluded that all season operation of heavy wheeled aircraft from snow runways is not a practical proposition for the short term. Other possibilities for all season operation of wheeled aircraft were considered. These included

(a) a conventional runway of rock-fill and gravel, (b) rock-fill and gravel over permanent ice, (.) a runway on coastal glacier ice, (d) runways on bare glacier ice at inland locations Rough cost estimates were made for each of the runway Rough cost estimates were made for each of the runway types that were considered. After examining the trends in antarctic aviation, the following recommendations were offered (1) develop a construction plan for a conventional runway at Marble Point, (2) proceed with site selection, equipment design, and development of ground transport for a wheel runway on the Ross Ice Shelf, (3) search for natural "blue ice" artifields at inland locations, especially locations that are not too far from the South Pole (Auth.)

ERUPTIONS FROM UNDER-ICE EXPLO-SIONS

Mellor, M., et al, Sep. 1988, 26p., ADA-207 497, 4

L'Heureux D.

EXPLOSIVES, VELOCITY MEASUREMENT, EX-PLOSION EFFECTS, UNDERWATER PHOTOGRAPHIC TECHNIQUES. PLOSION.

Struptions from under-ice explosions were recorded by a standard video camera and an ordinary motor-driven 35-mm camera. The records give the dimensions and velocities of the eruptions. Velocity, diameter, and height are related to charge depth and the results are compared with data for ordinary underwater explosions in ice-free water.

SP 88-15 ANALYTICAL METHOD FOR DETERMINING

TETRAZENE IN SOIL. Walsh, M.E., et al, Sep. 1988, 22p., ADA-201 138, 14 refs.

Jenkins, T.F. 43.1307

EXPLOSIVES, DETECTION, SOIL POLLUTION, MILITARY RESEARCH, CHEMICAL ANALYSIS, WATER POLLUTION, EXPERIMENTATION, ENVIRONMENTAL IMPACT, COMPUT-ER APPLICATIONS, STORAGE, MANUFAC-TURING.

An ion-pairing RP-HPLC method was developed to determine tetrazene in soil. The method involves extracting a 2 soil sample with 50 mL. of a solvent containing 55/45 v/v methanol-water and 1-decanesulfonic acid, sodium salt at 0.01 M concentration. The soil and extracting solvent are vortexed for 15 s and shaken on a platform orbital shaker for a period up to 5 hr. The extract is filtered through a 0.5-micron Millex SR filter and analyzed. Determination was achieved using an LC-18 column, a mobile phase of 2/3 v v methanol-water containing 1-decanesulfonic acid, sodium salt at 0.01 M concentration, and a UV detector set at 280 nm. The mobile phase pH was adjusted to 3 with glacial acetic acid, which was optimal for separation of tetrazene from potential interferences by other explosives Retention time was 2.8 min. Kinetic studies show maximum tetrazene recoveries are achieved from undried soil within 5 hr of shaking at room temperature. Refrigeration is required for extracts that are not analyzed immediately SR 88-16. An ion-pairing RP-HPLC method was developed to determine

SR 88.16 EFFECTS OF TEMPERATURE AND SPECIES

ON TNT INJURY TO PLANTS.
Palazzo, A J, et al, Sep 1988, 7p., ADA-200 323, 12

43-1140

PLANTS (BOTANY), SOIL POLLUTION, PLANT PHYSIOLOGY, DAMAGE, GROWTH, TEMPER-ATURE FFFFCTS

The studies tested the toxic effects of trinitrotoluene (TNT) The studies tested the toxic effects of trinitrotoliuene (TNT) to plants grown hydroponically. The first study tested the effect of temperature and TNT concentration on plant growth and the second tested the effect of TNT on various legumes and grass. The studies showed that the tolerance to TNT is related to both the genotypic characteristics of the plant and its rate of growth. Plants growing in more optimum environments and having a greater growth rate were more tolerant to the injurious effects of TNT. TNT toleran e was greater in grasses than in legumes. The growing points of plants originating from the crown were most tolerant to TNT injury.

SR 88-17 EFFECTS OF ALL-TERRAIN VEHICLE TRAF-FIC ON TUNDRA TERRAIN NEAR ANAK-TUVUK PASS, ALASKA.

Racine, C., et al, Sep. 1988, 12p., ADA-199 969, 17 refs

Johnson, L.A 43-1340

TUNDRA, ALL TERRAIN VLHICLES, ENVI-RONMENTAL MERALIN VEHICLES, ENVIRONMENTAL IMPACT, VIGIT VIION, TOPO-GRAPHIC FEATURES, DAMAGE, FROZEN GROUND STRENGTH, LICHENS, GROUND THAWING, THERMOKARST DEVELOPMENT Ny and eight wheel iight weight an terrain scholes (ATVs) (maints the Argo with low pressure, now ribbed tires) are currently used in the Anaktos in Piss, Vaska, a.ea for summer subsistence travel from the single into several Brooks Range valless. The environmental effects of summer ATV use are poorly understood. During the summers of 1285 and 1986, terrain disturbance at 31 sites representing trails over dry, moist and wet tundra was evaluated by rating the levels of soil exposure, vegetation destruction and microtopographic depression (ruts). Surface and frozen layer profiles across selected trail sites were also obtained, and trail visibility from the air and ground was rated. The levels of trail disturbance vary between valleys and generally decrease with distance from the village of Anaktuvuk Pass. Trails over dry tundra showed low to moderate terrain disturbance, the hard substrate and shallow organic cover resulted in low surface depression and low exposure of mineral soil However, vegetation disturbance was often high, particularly to lichens and tailer shrubs. These trails were generally of low visibility except where light-colored lichens were removed. Terrain disturbance on trails over most tundra varied from low to high. As long as cottongrass tussocks remained intact, and supported vehicle weight, terrain disturbance was low, once tussocks were destroyed, deep ruts developed quickly, followed by trail abandonment and formation of a new parallel track. Thawing increased under the highly disturbed trails, but thermokarst formation was infrequent because the ice content of the soils in the Anaktuvuk Pass area is generally low. Wet tundra trail sites showed moderate to high terrain disturbance with low vegetation disturbance but high microtopographic changes. On wet tundra, drivers often move to an adjacent new trail following only a few passes, reducing the disturbance in one track. Visibility was generally high because of standing water in the tracks and the presence of several parallel tracks.

IMPROVED TECHNIQUES FOR CONSTRUC-TION OF SNOW ROADS AND AIRSTRIPS. Lee, S.M., et al, Sep. 1988, 99p, ADA-100 113, 41

SOIL POLLUTION, SOIL WATER, EXPLOSIVES. SOIL COMPOSITION, CHEMICAL ANALYSIS, WATER CHEMISTRY.

WATER CHEMISTRY.

A protocol was developed for determining nitroaromatic and nitramine explosives by reversed-phase high-performance liquid chromatography on an LC-18 column. The method employs dilution of an aqueous sample 11 with methanol, filtration through a 0.5 micron Millex-SR filter, separation on the LC-18 column using a 1-1 water-methanol eluent, and determination by UV-254 nm. A careful comparison was made with an earlier standard protocol, which used separation on an LC-8 column with a 50 38-12 water-methanol-acctonitrile eluent. Overall, the new procedure provides better separation for a wider range of analytes and equivalent recovery for all analytes tested. The new procedure is particularly effective at separating TNT from tetryl, and it allows analysis of water and soil extracts using a single column and eluent combination.

DEVELOPMENT OF A MEMBRANE FOR IN-SITU OPTICAL DETECTION OF TNT.

WATER POLLUTION, GROUND WATER, EX-PLOSIVES, MILITARY FACILITIES, OPTICAL FILTERS, PHOTOMETRY, DETECTION, MEA-SURING INSTRUMENTS.

SURING INSTRUMENTS.

A membrane has been developed for in-situ determination of polynitroaromatic hydrocarbons in groundwater at levels as low as 10 ng/ml. A typical membrane is prepared by dissolving the following in tetrahydrofuran 0.5 g polytyring chloride; PVC), 0.2 ml. dioxyl phthalate to serve as a plasticizer and 0.12 ml. Jeffamine T403, a polyosyethylenea mise that tito acts as a plasticizer, as well as reacting with polynitroaromatic, hydrocarbons to produce a colored product. The membrane is formed by asting the solution and a giasy Petri dish with a diameter of 8 cm and anowing the solvent to slowly evaporate. Trace amounts of 2,4,6-timitrofoliuene (TNT), 1,3,5-timitrobenzene (TND), 2,4,5-timitrofoliuene (ZNS-TNT), and methyl 2,4-6 timitropheny intra mine (tetryl) react with the membrane op produce a visually observable reddish brown color. No pretreatment of water samples is required. Recoveries of 0.1 to 4.0 ppm. TNT from spixed groundwater ranged from 95. to 405. Direct analysis of water samples agreed with HPIC results.

ICE OBSERVATIONS ON THE ALLEGHENY AND MONONGAHELA RIVERS.

MONONGAHELA RIVER.

Corps of Engineers and National Weather Service records of ice conditions on the Allegheny and Monongahela rivers in PA and WVA were analyzed for seven recent winters. The on-ground observations recorded daily at a number of lock and dam locations were issued in the form of alphaniumene ice codes that included the coverage, type, thickness, structure and extent of river ice. These codes were used to graph ice conditions throughout the rivers to allow easier analysis of historical ice conditions. In addition, compansions were made between these observations and aerial videotapes and satellite images of the ice. Results of these complementary and should be used together whenever possible tary and should be used together whenever possible

SR 88-26 SNOWMELT INCREASE THROUGH ALBEDO REDUCTION.

Colbeck, S.C., Dec. 1988, 11p., ADA-204 523, 45 refs. 43-1927

SNOWMELT, ALBEDO, DUSTING, FREEZE THAW CYCLES, CLIMATIC FACTORS, SURFACE PROPERTIES, SNOW SURFACE, ICE MELTING, ABLATION.

MELTING, ABLATION.

Due to changing surface conditions, the albedo decreases naturally as snow ages. The details of the melting processes have been investigated for some years and much is known about the effect of each process and the interactions among them. Albedo has attracted a lot of attention because of recent interest in snow-climate feedback, and the reduction in albedo by darkening agents has been studied and practiced extensively. Although much is known about albedo reduction, the optimum design of a field program to enhance snow melting requires too much information to be easily achievable. The relevant snow properties and processes are described here along with some field observations. Much research must still be done to provide guidelines for the use of snow darkening agents in any particular environment.

44-3015 CONSTRUCTION MATERIALS, BUILDINGS, POLLUTION, RAIN, PRECIPITATION (METEOROLOGY), CHEMICAL PROPERTIES, STATISTICAL ANALYSIS, URBAN PLANNING.

The overall purpose of this research was to develop a data base of building material types sensitive to acid deposition. The objective of this study was to address several statistical questions about the data base of sampled building materials for four cities, which included. New Haven, Connecticut, Portland, Maine: Pittsburgh, Pennsylvania, and Cincinnati, Ohio. The four cities were mapped into sampling frames, which divided the city into similar areas. Use of the sampling frames assumed that the location, form and function of buildings, and the amount and kind of building materials, are related to the land use. Information on building materials for about 70 buildings per sampling frame were inventoned. are related to the land use Information on building materials for about 70 buildings per sampling frame were inventored for each city. The statistical analyses of the data base for each city included comparing building sizes with the size of the sampling footprint, determining the distribution of buildings per footprint for each sampling frame, and examining the distribution of material types as a function of building size and building type for each sampling frame

RESPONSE OF PAVEMENT TO FREEZE-THAW CYCLES: LEBANON, NEW HAMP-SHIRE, REGIONAL AIRPORT.

Allen, W.L., et al, Jan. 1989, 31p., ADA-205 559, 6 refs.

Quinn, W.F., Keller, D., Eaton, R.A.

43-2809 PAVEMENTS, RUNWAYS, FREEZE THAW CY-CLES, FROST HEAVE, FROST PROTECTION, UNITED STATES—NEW HAMPSHIRE—LEBA-NON.

In 1978 reconstruction was begun on the runway of the Lebanon Regional Airport, Lebanon, New Hampshire The runway had experienced severe differential frost heaving and Leoanon Regional Airport, Leoanon, New Hampsnier Inc.
runway had experienced severe differential frost heaving and
cracking during the previous three winters, which had resulted
in closure of the facility during periods of extreme roughness.
At the request of the Federal Aviation Administration and
in conjunction with the reconstruction, CRREL undertook
to study the newly constructed pavements to investigate
the relationships between weakening of the pavements, frost
heave of the pavement surfaces and the position of the
freezing front. Temperature sensors were placed within
the newly constructed pavement sections, and during the
winters of 1979, 1980 and 1982 temperature data were
recorded, and level surveys and repeated plate bearing tests
were performed in order to provide data for the investigation.
The three pavement sections were constructed to investigate
the effect of section thickness on the level of frost protection
provided The sections consisted of 4 in of asphalt concrete,
6 in. of crushed gravel and 22, 30 and 38 in of wellgraded sand subbase material. The 48 in section provided
the highest level of frost protection to the subgrade However, all three pavement sections maintained resilient stiffness the highest level of frost protection to the subgrade of the serial three pavement sections maintained resilient stiffness values during the spring thaw period on the order of two to three times that of the pavement before reconstruction Also, frost heave in all sections was reduced to levels that would not cause difficulty for aircraft using the facility

RADAR PROFILING OF NEWTON AIRFIELD

IN JACKMAN, MAINE. Martinson, C.R., Feb. 1989, 9p., ADA-207 303, 2 refs.

FROST HEAVE, INSULATION, PAVEMENTS. RADAR.

During Apr. 1987 ground-penetrating radar was used to observe subsurface conditions of Newton Field, an airfield in Jackman, ME. It was constructed in 1986, with insulation observe substance conditions of Newton Frict, an affrication for Jackman, ME. It was constructed in 1986, with insulation used as part of its subgrade. A road near the artifield that was constructed in the same fashion, except without the insulation, was also profiled for comparison. The survey was to document conditions of nonuniform frost heaving and, if possible, frost depth. Radar data, collected with a 900-MHz antenna, showed that the insulation beneath the runway apparently varied in depth from approximately 5 to 24 in. Frost depth, however, could not be determined with the 900-MHz antenna.

TERPRETATION, AERIAL SURVEYS.

QuickDraw is the graphical operating language for the Apple Macintosh. Standard binary data formats are currently used to import and export satellite images to geographic information- and image-processing systems. These data structures provide a standard sequential method to read and write large volumes of information in a semicompressed format. While the binary structure is adequate for strict import and export of image data, it is poorly adapted to fast image-processing at the microcomputer level. In this study, new data structures are investigated that use operating codes to quickly convert raster binary image data and vector overlay files into a high-speed graphical language for efficient display and processing. Binary data is converted into "picture handles" of variable size and resolution using 2-byte operating codes to symbolize the graphical process As a result, images are drawn as objects that may be coupled as independent vector components in multiple bit planes. The bit planes may be specified for each pixel to support 24- and 32-bit color of both raster and vector data. The efficiency of these structures allows the user to display 1024 x 1024 scenes in multiple overlapping windows using simple. 24- and 32-bit color of other inster and vector data. The efficiency of these structures allows the user to display 1024 x 1024 scenes in multiple overlapping windows using simple Cut/Copy/Paste commands. In addition, the use of operating codes allows an analyst to quickly store and retrieve archived images in their compressed form using simple "scrap manager" techniques. Early results for this technique indicate that converted vector overlays may be compressed by a factor of 8 and SPOT images (depending on scene diversity) by a factor of 2. More significantly, images that typically require 4 min to load from binary may be displayed in fractions of a second using the new display method and resultant operating codes. In its present form, the software provides a gateway for users of image data to display multiple bands of information quickly, and to vary hue, saturation, brightness, and resolution levels on the microomputer New utilities will include image export into the PNTG, PHCA, EPS, and TIFF formats for export compatibility with Postscript page-layout software and video image-processing systems. with Positing systems

INFLUENCE OF WELL CASING COMPOSI-TION ON TRACE METALS IN GROUND WA-TER.

Hewitt, A.D., Apr. 1989, 18p., ADA-208 109, 12 refs.

GROUND WATER, WELL CASINGS, WATER POLLUTION, ENVIRONMENTAL IMPACT.

Experiments were conducted to determine the concentration Experiments were conducted to determine the concentration dependence of trace inorganic priority pollutants (Ax. Cd. Cr and Pb) in ground water solutions exposed to polyvinyl, hio ride (PVC), polytetrafluorothylene (PTTE) and two types of stainless steel (SS304 and SS316). The test design used a factorial screening matrix with two concentrations of metals (Ax-Cr-Pb. Do and 10 microgram'l. Cd. 10 and 2 microgram'l.), pH (5.8 and 7.7), and total organic carbon (natural and natural plus 5 mg·l. humic acid) as variables Samples containing well casings and controls without pipe sections were run as duplicates. Aliquots were removed from all of the solutions after 0.5. 4, 8.24 and 7.2 hours Aqueous metal concentrations were determined by graphite furnace atomic absorption spectroscopy. The results showed furnace atomic absorption spectroscopy

The results showed

PTFE to have no significant influence on the metals monitored
under any of the groundwater conditions

Metal concentra-

tions in ground water exposed to SS316 and SS304 had large random variances believed to be caused by surface oxidation of the stainless steel. PVC had a more active surface than PTFE in terms of both sorption of Pb and release of Cd.

COMPACTED-SNOW RUNWAYS: GUIDE-LINES FOR THEIR DESIGN AND CONSTRUC-TION IN ANTARCTICA.

Russell-Head, D.S., et al, Apr. 1989, 68p., ADA-208 910. Refs. passim.

SNOW PHYSICS, SNOW COMPACTION, SNOW (CONSTRUCTION MATERIAL), RUNWAYS, DESIGN, PENETROMETERS, ANTARCTICA.

Only small areas near the margins of the ice cap in Antarctica Only small areas near the margins of the ice cap in Antarctica are ice-free, and only a few of these exposed sites are suitable for the construction of conventional runways. Wheeled aircraft have operated successfully on hard see ice and exposed glacial ice, and skis have been fitted to a wide range of aircraft for use on snow. There has been a resurgence of interest in making snow runways suitable for use by conventional wheeled aircraft. Laboratory and field work has confirmed that low-density surface snow can be compacted in several ways to yield a strong, uniform, load-bearing pavement that can support heavy wheeled aircraft. The Soviets have constructed several full-scale runways in Antarctica. This report provides some of the Icefaical Ine Soviets have constructed several full-scale runways in Antarctica. This report provides some of the technical background for the design and construction of compacted-snow runways in Antarctica. The technology is not particularly difficult, and it is likely that the next few decades will see substantial changes to antarctic air transportation as more snow runways are constructed throughout the continuous nent. LAND MINES IN WINTER.
Richmond, P.W., May 1989, 10p., ADB-134 433, 26 refs.

43-4041

MINES (ORDNANCE), MILITARY OPERA-TION, COLD WEATHER PERFORMANCE, RAIN, FROZEN GROUND, SNOW DEPTH.

RAIN, FROZEN GROUND, SNOW DEPTH.

A number of questions about the use and performance of land mines in winter were investigated during the past 7 years as part of the Mine/Countermine Research Program of the Corps of Engineers. The environmental effects of winter on both conventional and scatterable mines are discussed. Recommendations are made to enhance the efficient use of mines in winter, many of these suggestions have already been published in U.S. Army doctrinal literature. The effects of thawing and freezing soil, deep snow, triplines in snow and freezing rain on conventional mines (mines that are not designed to self-destruct) are discussed. A general analysis of the behavior of scatterable antitank mines in snow is introduced and results of experiments using the GEMSS and RAAMS are presented.

SR 89-12 POROUS PORTLAND CEMENT CONCRETE AS AN AIRPORT RUNWAY OVERLAY: LABORA-TORY EVALUATION.

43-3070

CONCRETE PAVEMENTS, RUNWAYS, CON-CRETE STRENGTH, COLD WEATHER PER-FORMANCE.

FORMANCE.

A company recently introduced a special mixing method for producing stronger porous portland cement concrete than that made using standard mixing techniques. The process, which includes no admixtures, relies on a patented high-speed mixer to achieve the claimed results. The material, as designed by the company, was evaluated under laboratory conditions to determine its suitability for use as an overlay on concrete runways in the cold regions included strength, permeability and freeze-than tests. Concrete strength was improved whenever the high-speed mixer was used. However, the improvements were erratic, ranging from 2 to 37° stronger than the same concrete mixed using the standard technique. The mix design used by the company was fairly permeable to water but was not resistant to freezing and thawing when water was ponded it. Further improvements are needed in both the consistency of strength and the resistance to frost of this material before it can be considered for cold regions applications.

J.S. 41.3894

EQUIPMENT. DESIGN CRITERIA, COLD WEATHER OPERATION, COLD WEATHER PERFORMANCE, LOW TEMPERATURE RE-SEARCH, TEMPERATURE EFFICES

Designing equipment for arctic environments requires special considerations from the design enginee. I ow temperatures

and harsh environments place special demands on equipment and components. Many materials in common use will experience drastic changes in physical properties, resulting in catastrophic failure of the systems in which they are in catastrophic failure of the systems in which they are incorporated. Components may no longer meet original specifications, and instrumentation may not work properly. This design guide should familiarize the design engineer with the factors that must be considered when designing for the arctic environment. A list of environmental factors and how they may affect a design is first presented. Then, a general design procedure is presented and a detailed analysis of problems and solutions for materials, components and systems follows:

EFFECTS OF SOIL COVERS ON LATE-FALL SEEDINGS OF FOUR TALL FESCUE VARIE-TIES.

Palazzo, A.J., June 1989, 5p, ADA-212 203, 20 refs

GRASSES, COLD WEATHER SURVIVAL

GRASSES, COLD WEATHER SURVIVAL.
Soil covers promote seed germination and plant growth at suboptimum temperatures by conserving heat near the soil surface. This conservation of heat results in a higher soil surface temperature than in uncovered soil. The result is succulent seedlings that may be more susceptible to premature death during winter and reduced growth the following season. The objectives of this study were to evaluate the effectiveness of soil covers for promoting seed germination in the fall and to observe the effects of soils covers on plant growth and development. A field study was conducted using Clemfine, Misstang, Rebel and Rebel II varieties of tall fescue (Festuca anudanacea Schreb) sown in mid-Oct in New Hampshire using a randomized block design. Half of each plot was covered with a spun-bonded polypropylene

soil cover The cover remained on the plots until the following June. It enhanced seedling emergence in the fall for all four varieties and subsequent regrowth during May for all varieties except Rebel. Very little extra growth May for all varieties except Rebel. Very little extra growth was observed under the cover during Apr., when average ambient temperatures were shout 6.2 C. Analysis of tissue sampled in June showed that the carbohydrate content was lower with the higher-pielding varieties. Higher-pielding varieties that had been covered showed lower concentrations of fructans in leaves, but the levels were not sufficient to affect summer growth. No differences in carbohydrate concentrations between varieties were found. Test results show that the use of soil covers promoted seed germination of late fall seeding and improved grass growth through the following Aug. following Aug.

SINGLE FIBER MEASUREMENTS FOR REMOTE OPTICAL DETECTION OF TNT.
Zhang, Y., et al, May 1989, 7p., ADA-209 995, 5 refs. Seitz, W.R., Sundberg, D.C. Seitz, W. 43-3870

EXPLOSIVES, WATER POLLUTION, DETECTION, SPECTROSCOPY, GROUND WATER, MEASURING INSTRUMENTS.

Single fiber optical measurements have been used to follow changes in the color of an initially clear poly(vinyl chloride) (PVC) membrane, which reacts with aqueous 2,4,6-trinitrotol-une (TNT) to form a colored product that absorbs strongly at 500 nm. Attempts to make this measurement via the at 500 nm. Attempts to make this measurement via the effect of the colored product on the emission spectrum of a fluorophor incorporated into the PVC membrane were unsuccessful. However, single fiber absorption measurements were successful. Refractive index matching and a reflector behind the membrane to increase reflected intensity were essential to keeping the stray light levels small relative to the signal of interest. To compensate for drift, the reflected intensity at 500 nm is measured relative to the reflected intensity at \$24 nm, a wavelength where intensity is not affected by color formation in the membrane. The rate at which the ratio of intensity at 500 nm to intensity at \$24 nm increases is a function of TNT concentration. It is estimated that TNT levels below 0.10 ppm can be measured by this technique.

ICE RUNWAYS NEAR THE SOUTH POLE. Swithinbank, C., June 1989, 42p., ADA-211 606, 7

43.4508

ICE RUNWAYS, COLD WEATHER CONSTRUC-AERIAL SURVEYS, ANTARCTICA— GLACIER, ANTARCTICA—HOWE, TION, AERIAL MOUNT.

MOUNT.
Following an examination of air photographs of the Transantarctic Mountains, 37 blue-ice areas were reconnostered from the air, using a skr-wheel Twin Otter operating from the South Pole. Two sites were selected as potential airfields for conventional transport aircraft, and ground surveys were made. On the Mill Glacier at 85 06'S, 167 15'E there is an area of smooth and level ice which gives a 7 km run directly into the prevailing wind. Five wheel landings were made there. Alongside Mount Howe there is a large area of level ice at 87 20'S, 149 50'W. It offers a 7 km runway, but there is a strong crosswind component from the prevailing wind and some bumps on the ice surface need to be planed off. Eight wheel landings were made at Mount Howe. (Auth)

COMPARISONS OF LOW CONCENTRATION MEASUREMENT CAPABILITY ESTIMATES IN TRACE ANALYSIS: METHOD DETECTION LIMIT AND CERTIFIED REPORTING LIMIT. Grant, C.L., et al, June 1989, 21p., ADA-211 829, 19

SOIL POLLUTION, CHEMICAL ANALYSIS, WASTES, SPECTROSCOPY.

SOIL POLLUTION, CHEMICAL ANALYSIS, WASTES, SPECTROSCOPY.

Two large data sets were obtained over a four-day period for graphite furnace atomic absorption spectroscopic measurement of copper (Cu) and reversed-phase high performance liquid chromotographic determination of dinitrobenzene (DNB) at a number of concentrations near the lower limit of measurement. Low concentrations measurement espability estimates for each analyte were obtained using the Environmental Protection Agency's MDL (method detection limit) protocol and the U.S. Army Toxic and Hazardous Materials Agency's CRL (certified reporting limit) protocol For DNB, analytical variance was found to be homogeneous over the concentration range examined and MDL estimates were independent of concentration over the range of concentration examined MDL estimates varied by as much as a factor of three from day to day, emphasizing the uncertainty in these estimates. CRL estimates varied to about the same extent and were numerically quite similar to MDLs when equivalent false positive and false negative risks were used. For Cu, analytical variance was found to be proportional to concentration. Thus CRL estimates were every dependent on the concentration range examined MDLs were less sensitive to this problem. Recommendations regarding the choice of target reporting limits for the CRL protocol were made. The influence of risk assumptions no both MDL and CRL estimates was examined and recommendations for modifications to both procedures made.

to incorporate an operational false negative-risk appropriate to the problem at hand. A case was made for using outlier tests to edit data used to estimate low concentration measurement capabilities.

IMPROVING SNOW ROADS AND AIRSTRIPS

IN ANTARCTICA. Lee, S.M., et al, July 1989, 18p., ADA-211 588, 7 refs. Haas, W.M., Brown, R.L., Wuori, A.F.

SNOW ROADS, RUNWAYS, ANTARCTICA—MCMURDO STATION, ANTARCTICA—AMUNDSEN-SCOTT STATION.

MCMURDO STATION, ANTARCTICA—AMUNDSEN-SCOTT STATION.

During the 1986-1987 austral summer, snow road and runway test lanes were constructed at McMurdo Station and at South Pole Station. These lanes were monitored during Dec. 1986. Jan. 1987, and again in Jan. 1988. Test sections were constructed of 1) tractor-compacted snow topped with a 15-cm thick layer of rotary blower processed snow, 2) rotary processed and compacted snow in 15-cm layers to a depth of 60 cm, 3) rotary pr. seed and compacted snow in 15-cm layers to a depth of 60 cm, 3) rotary pr. seed and compacted snow in 15-cm layers mixed at 5% by volume, and 4) rotary—seed snow with 19% sawdust by volume. These test see, and monitored by obtaining temperature at. Rammsonde hardness profiles, California B. Clegg surface strength values, and testing for stand traffic. It was concluded that wood stop rocessed snow in amounts of 5% to 10% volume significantly increases the strength of the resul. Snow road or runway. This increase was greater at h. Murdo than at the South Pole, appearing to be a function of snow temperature. Adequate strengths of the snow/sawdust mixtures were achieved for limited use by wheeled C130 aircraft, but additional processing with heat, water or added compaction appears necessary to produce a 25-cm-thick surface layer sequante for more frequent use and to accommodate wheeled C141 aircraft. At McMurdo, it was found that the sawdust was not effective in maintaining the integrity of the surface for traffic during the thawing season without additional maintenance, whereas at the South Pole, thawing was not a problem since temperatures remained well below the melting point. It was concluded that the McMurdo snow roads were not constructed adequately early in the season to prevent failure and, therefore, required an undul, high maintenance effort during the warm season. It is also recommended that the future roads be constructed by depth processing with a rotary miller or blower. It is also recommended that the future roads be constructed

ESTIMATION OF TIME TO MAXIMUM SUPERCOOLING DURING DYNAMIC FRAZIL ICE FORMATION.

Daly, S.F., et al, July 1989, 13p., ADA-212 204, 12 refs

Axelson, K.D.

FRAZIL ICE, ICE FORMATION, RIVER ICE, SUPERCOOLING, HEAT LOSS, ANALYSIS (MATHEMATICS).

(MATHEMATICS). Time to insainum supercooling is a parameter that can be easily measured during experiments on the dynamic, nonequilibrium stage of frazil ice formation. Mereler's analytical expression is applied to a number of experiments in which the time to maximum supercooling was measured. In each of the experiments, the heat loss rate and turbulent dissipation rate were reported or could be determined from the experiment description. The secondary nucleation was set at the value of 40,000,000,000 nuclel/erg suggested by Mercier, and the seeding rate optimized to reproduce the experimental results. An inverse relationship was found between the coldroom temperature at which the experiment was conducted and the seeding rate. The optimized seeding rates varied from 2.7 to .000075 crystals/sq cm s. The implications for frazil ice formation in rivers and streams are discussed. are discussed.

PROCESSING, COMPOTER PROCERAMS.

A software system, DCP, FOR, was developed to provide a convenient and efficient method of decoding, reducing, and storing data from Data Collection Platform (DCP) networks transmitted through the Geostationary Operational Environmental Satellite (GOES) data collection system. The software system includes a simple means of defining the arrangement of sensors, at a DCP site that can be easily updated if the sensor arrangement is changed or the sensors

modified. Any incer data reduction procedure can be processed. Precise temperature measurements using individually calibrated thermstors can be processed through the use of voltage divider circuits, nonlinear resistance to temperature calibration, and impedance mismatch detection. temperature campration, and impedance minimated detection and correction. The system can process data from DCPs manufactured by four companies. User-defined maximum and minimum limits determine the acceptability of the processed data. Data values not within these limits or missing data are flagged with a missing value marker. The database created by the system is independent of the particular sensor arrangement at any DCP site. The data can be easily transferred to other database systems.

SR 89-30 OPTICAL MEASUREMENT OF PRECIPITA-

Koh, G., Sep. 1989, 13p., ADA-214 357, 11 refs. 44-694

PRECIPITATION (METEOROLOGY), METEOROLOGICAL INSTRUMENTS, SNOW-PALL, RAIN, SNOW OPTICS, MEASURING IN-STRUMENTS, ANALYSIS (MATHEMATICS).

STRUMENTS, ANALYSIS (MATHEMATICS). A simple optical device is used to measure changes in light intensity caused by precipitating particles as they fail through a beam of light. The intensity changes are analyzed in the amplitude and frequency domains to obtain information shout precipitation. Tests conducted in snow and in rain show that the optical device can be used for characterizing precipitation with finer time resolution then conventional methods. Rain rates can be accurately monitored; however, errors in snow rates can be as high as a factor of two. Number flux measurements suggest that periodic trends may exist during snow and rain. Power spectra of the intensity changes show that spectral signatures exist for different types of precipitation.

VEHICLE MOBILITY ON THAWING SOILS. Shoop, S.A., Sep. 1989, 16p., ADA-215 148, 21 refs.

GROUND THAWING, SOIL TRAFFICABILITY, FREEZE THAW TESTS, SOIL TESTS, SOIL STRENGTH, THAW DEPTH, FROST ACTION, TRACTION.

Although vehicle mobility in soft and wet soil has been Attnough ventice moonly in soil and wet soil has been studied in the past, the more complex problem of vehicle mobility on thawing soils has not been addressed. This problem is being examined in CRREL's Frost Effects Research Pacility (FERF), where field-scale testing can be conducted under controlled conditions. The soil is frozen and then thawed to the desired test conditions.

Traction and motion thawed to the desired test conditions. Traction and motion resistance are measured using an instrumented vehicle. To date, mobility testing has been conducted for nine different thawing conditions of a frost-susceptible silt. The failure mechanisms of the tire-soil interaction were observed, that soil strength was calculated, and vehicle performance was analyzed. For the tire and soil conditions tested, the initial failure of the tire-soil interaction is totally within the soil. At higher tire slip the failure occurs at or near the tire-soil interface. The shear strength data calculated from the vehicle test results indicate that the soil is basically frictional in behavior, with little or no cohesion; however, there is apparent cohesion from soil tension at low moisture contents. Of the soil parameters measured, vehicle traction is most strongly influenced by the soil friction. In turn, soil friction and cohesion are influenced by moisture content, density and thaw depth. content, density and thaw depth.

LEACHING OF METAL POLLUTANTS FROM FOUR WELL CASINGS USED FOR GROUND-WATER MONITORING.

Hewitt, A.D., Sep. 1989, 11p., ADA-215 239, 18 refs.

WATER POLLUTION, GROUND WATER, WELL CASINGS, LEACHING, CHEMICAL ANALYSIS, IMPURITIES, WATER PIPES.

IMPURITIES, WATER PIPES.
Polytetrafluorethylene (PTPE), polyvinylchloride (PVC), stainless steel 304 (SS 304) and stainless steel 316 (SS 316) well casings were tested for suitability for ground-water monitoring. A laboratory experiment, testing for the leaching of Ag, As, Ba, Cd, Cr, Hg, Pb, Se and Cu, was run in riplicate by exposing sections of the well casings to ground water for four periods ranging from 1 to 40 days. The results showed that PTPB did not leach any of the nine analytes studied, while SS 316 and PVC showed significant leaching of Cr, Cd and Pb; SS 316 also leached significant

amounts of Ba and Cu. Stainless stee! 304 showed signification leaching of Cr and Pb. In every case where contamination was observed, the release of metal analyte, when averaged over all of the exposure periods, was the greatest from either 88-304 or 88-316. Released contaminants were surbed back onto the well casings in several cases.

SR 89-33 ALTERNATIVE METHODS OF USING STB FOR DECONTAMINATION AT LOW TEMPERA-TURES. Walsh, M.E., et al, Sep. 1989, 13p., ADB-139 077, 7

WINTER HABITATS OF ATLANTIC SALMON, BROOK TROUT, BROWN TROUT AND RAINBOW TROUT; A LITERATURE REVIEW.

Calkins, D.J., Oct. 1989, 9p., ADA-214 832, 44 refs ANIMALS, RIVER ICE, PHYSIOLOGICAL EF-

FECTS, ECOLOGY, ICE CONDITIONS, ICE COVER EFFECT, COLD WEATHER SURVIVAL. COVER EFFECT, COLD WEATHER STRVIVAL.

A review of winter habitat studies lh ice-covered streams for four species of salmonid provided some general information on substrate conditions and focal point velocities and depths. All species of fry are found at depths less than 40 cm and at velocities of 10 cm/s or less; juveniles of all species are found at velocities of cess than 15 cm/s. A lack of continuous physical, chemical and biological measurements throughout the ice-covered season was a common deficency of the studies reviewed. The interaction of the ice cover with other physical processes in the stream was restrict adith other physical processes in the stream was rarely ad-

ANALYTICAL METHODS FOR DETERMINING NITROGUANIDINE IN SOIL AND WATER. Walsh, M.E., Nov. 1989, 27p., ADA-216 615, 9 refs.

POLLUTION, SOIL CHEMISTRY, WATER POLLUTION, GROUND WATER, EXPLOSIVES, CHEMICAL ANALYSIS.

CHEMICAL ANALYSIS.

Methods were developed for determining nitroguanidine in soil and water. The soil method involves extracting a 2-g sample with water using an ultrasonic bath. Soil extracts and water samples are filtered through a 45-micron membrane prior to determination by RP-HPLC. Separations are achieved on a mixed-mode RP18/cation column clusted with 1.5 mL/min of water; detection is by UV (lambda=263 nm). Certified reporting limits were estimated at 5.0 microgram/L for water and 0.5 microgram/L for soil.

SR 89-36 PERFORMANCE OF WALL COATINGS FOR CONCRETE AND MASONRY BUILDINGS IN ALASKA.

Bayer, J.J., Jr.

44-1878 PROTECTIVE COATINGS, WALLS, MILITARY FACILITIES, VAPOR BARRIERS, BUILDINGS, THERMAL INSULATION, WEATHERPROOF-

Coatings traditionally have been applied to the Army's concrete Coatings traditionally have been applied to the Army's concrete and masonry buildings in Alaska to improve their appearance and to increase their weather resistance. Unfortunately, these materials have not always lasted as long as desired, resulting in high maintenance costs. A visual examination of 151 buildings at three military installations in Alaska revealed that water vapor condensation was a major cause of premature coating failure. This moisture not only caused coatings to deteriorate, but when it froze, it caused spalling of the wall. Laboratory tests proved that coatings with the best field performance had the highest permeance to water vapor. This auggested that more attention be given water vapor. This suggested that more attention be given to defining and selecting breathable coatings.

ACCURACY AND PRECISION OF GOES DATA COLLECTION PLATFORMS FOR TEMPERATURE MEASUREMENTS.

Daly, S.F., et al, Dec. 1989, 14p., ADA-218 798. Clark, C.H., Pangburn, T.

44-2846

REMOTE SENSING, ACCURACY, DATA TRANSMISSION, TEMPERATURE MEASURE-MENT, EQUIPMENT.

This report describes an analysis of the accuracy and precision of data transmitter. by 12 Data Collection Platforns (DCPs) over a one-month period. The DCPs were installed on the Monongahela, Ohio and illinois rivers A reference resistor with a known and stable resistance was installed at each DCP site. Comparison of the resistance calculated from the transmitted information with the actual resistance of the reference resistor allowed the accuracy and precision of the measurements made by the DCP to be determined. Four brands of DCPs were included in the test; two had 8-bit resolution and two had 12-bit resolution. The results were analyzed with respect to the nominal accuracy provided by the manufacturer and the expected analog-to-digital quantizing error. This error explained most of the imprecision of the 8-bit DCPs but only part of the imprecision of the 12-bit DCPs. A large bias for some of the results was apparently caused by an impedence mismatch. A means for correcting the data based on the reference resistor measurement is proposed.

This report reviews literature on the influence of major parameters on composting, with emphasis on temperature and explosives. Heat energy is produced by composting as a result of the microbial conversion of chemical energy an a result of the microbial conversion of chemical energy of thermal energy. Hence, heat production and transfer, the influence of engineering design on compost pile temperatures, and the control and measurement of compost pile temperatures are also examined. In addition, the report includes a general discussion on composting, fundamental composting principles, available types of composting systems, applications of composting technology, and the established parameters influencing composting under various environmental conditions that may be applicable to cold regions treatment of hazardous waste.

ENVIRONMENTAL TRANSFORMATION PRO-DUCTS OF NITROAROMATICS AND NITRA-MINES: LITERATURE REVIEW AND RECOM-MENDATIONS FOR ANALYTICAL DEVELOP-MENT

Walsh, M.Z., Feb. 1990, 21p., ADA-220 610, 57 refs

EXPLOSIVES, SOIL POLLUTION, WATER POL-PACT, SOIL CHEMISTRY, CHEMICAL ANALYSIS, DECOMPOSITION.

The literature describing the environmental transformation of organic explosives and related compounds is reviewed in an attempt to identify those byproducts for which certified analytical methods should be developed. Among those compounds identified are TNT reduction products (aminodinirotoluenes and diaminonitrotoluenes) and coupling products (azoxytoluenes). The development of methods is also recommended for the amno derivatives of DNT, TNB and DNB, as well as the nitroso derivatives of HMX and RDX.

FREEZEUP DYNAMICS OF A FRAZIL ICE SCREEN

Axelson, K.D., Feb. 1990, 8p., ADA-219 588, 12 refs.

FRAZIL ICE, RIVER ICE, ICE CONTROL, ICE BOOMS, FREEZEUP.

Fence booms made of wire mesh screen have been prop as economical, temporary frazil ice control structures. T screens incorporate frazil n = as it freezes to the screen material, eventually forming a frazil tee dam and raising the water level at a specified location. The purpose of raising the water level is to allow the formation of a stable tine water level at a specified location. The purpose of rasing the water level is to allow the formation of a stable ice cover that will incorporate still more frazil ice through hydraulic thickening of the cover and deposition bener the cover. A series of experiments examining the freezeup and blocking dynamics of an expanded metal frazil ice screen were conducted using both an impermeable barner a.. of frazil ice. A qualitative analysis of the complex frazil ice accumulation process indicated three phases of blocking—an onfice flow stage, a transition stage, and a permeable flow stage. A fourth phase, weir flow, was observed in some cases, and is expected to occur in prototype structures. High downstream flow velocities were associe with the orifice and transition stages. Downstream, ocities decreased during the permeable flow stage, although piping resulted in velocity jets. The test results indicate that a rapidly and completely blocked screen is desirable to minimize the time during which high downstream velocities, which lead to bed scour, occur.

SR 90-05

X RAY PHOTOGRAPHY METHOD FOR EX-PERIMENTAL STUDIES OF THE PROZEN FRINGE CHARACTERISTICS OF FREEZING

Akagawa, S., Feb. 1990, 69p., ADA-222 448, 15 refs.

SOIL FREEZING, FROST HEAVE, X RAY ANALYSIS. ICE LENSES. GROUND ICE. TEMPERA-TURE MEASUREMENT.

YSIS, ICE LENSES, GROUND ICE, TEMPERATURE MEASUREMENT.

The objectives of this report are to demonstrate a useful method for observing froe heave in freezing soil and to evaluate the method for the study of frozen fringe characteristics. X-ray photography of lead spheres containing thermocouples was tested in conjunction with frost heave tests. By applying image-processing techniques for determining the coordinates of the spheres, it is possible to obtain precise temperature profiles and determine, the deformation in freezing soil. Strin and strain rate data calculated from the coordinates of the lead spheres and the temperature profiles show when, where and how much deformation (heaving and consolidation) has taken place in the freezing soil. The temperature and strain field around the frozen fringe were also observed However, the method of determining the frozen fringe location from the location of the warmest ice lens was found to be located between the warmest visible ice lens and the 0 C isotherm. This was especially true during transient heaving, which occurs while the 0 C isotherm penetrates into the unfrozen soil. I are studying the precise deformation characteristics of the frozen fringe, further precise analysis of the X-ray photo's intensity profile will be needed to convert it to a strain profile. The accuracy and spacing of the temperature measurements in the frozen fringe, and there is a need for measurement methods that are more accurate than conventional temperature exposition. is a need for measurement methods that are more accurate than conventional temperature sensors

SALMON RIVER ICE JAM CONTROL STUD-IES: INTERIM REPORT.

WELL CASINGS, GROUND WATER, SOIL POL-LUTION, WATER POLLUTION, WASTES, SCANNING ELECTRON MICROSCOPY, COR-WASTES, ROSION, PIPES (TUBES), SURFACE PROPER-

TIES.

This preliminary study was undertaken to assess how the surface structural characteristics of four common well casing materials—polyvinyl chloride (PVC), Teflon (polytetrafluorocitylene, PTFE), stainless steel 304 (SS04) and stainless steel 316 (SS346)—are affected by exposure to an aqueous solution containing tetrachloroethylene, toluene, p-dichloroenezene and o-dichlorobenzene in concentrations near their solubility. Casing samples that had been exposed to a test solution for 1 week, 1 month and 6 months were examined with a scanning electron microscope (SEM) and c. mpared with control samples placed in well water for an equivalent time period. Pieces of casing that had not been placed in any aqueous solution were also examined and are assumed to be representative of the initial structure of the casing's surface. These organics are of concern at hazardous wastic sites, where they often occur in ground water. The observations indicate that the surface characteristics of PVC, SS316 and SS304 did not change when exposed to the organic aqueous solution. The surface variability and lack of distinguishing features at high magnification made it difficult to tell if the PTEE surface had changed. However, no obvious changes (swelling, pitting etc.) were However, no obvious changes (swelling, pitting etc.) were

CASE STUDY OF POTENTIAL CAUSES OF FROST HEAVE.

Henry, K.S., May 1990, 35p., ADA-224 071, 17 refs.

FROST HEAVE, PAVEMENTS, SOIL FREEZING, RUNWAYS, FROST PROTECTION, FROST PENETRATION, SUBGRADE SOILS.

PENETRATION, SUBGRADE SOILS.
Frost action beneath pavements can lead to several problems, including thaw weakening, which causes cracking and subsequent pumping of fine soil particles onto the surface, as well as hazardous conditions caused by differential heaving This stufy examined data and frost-susceptible soi. collected during the winter of 1985-86 at Ravalli County Airport, Hamilton, MT, to determine potential causes of frost heave Variables analyzed were depth to water table, depth of frost penetration, maximum frost heave, and soil moisture tension and soil temperature with depth. Analysis of the field data revealed the possibility that hydraulic conductivity of subgrade soils and rates of heat loss in the soil may be limiting frost heave rates. Soil density and depth to water table may also be factors affecting amounts of frost heave. Furthermore, the base course "gravel" used at the airport contained considerable amounts of fines and did heave somewhat in laboratory tests. Recommendations for design changes to reduce frost heave at Ravalli County Airport were made.

Deployment alternatives for the US Army Ribbon Bridge on a waterway covered with 24-in-thick ne were investigated lee clearing methods using a buildozer, ice tongs, chain saws and the hoists available on the bridge transporter trucks all worked with varying degrees of success. Sections of the Ribbon Bridge were deployed directly on the ice cover, a procedure that has potential but that also has problems and unanwered questions. and unanswered questions

SR 90-11 INVESTIGATION OF THE LIZ-3 DEW LINE STATION WATER SUPPLY LAKE.

Kovacs, A., Apr. 1990, 10p., ADA-222 469, 6 refs.

WATER SUPPLY, FROZEN LAKES, LAKE WA-TER, LAKE ICE, RADAR PHOTOGRAPHY, SUB-SURFACE DRAINAGE, SUBPERMAFROST GROUNDWATER, PERMAFROST BENEATH LAKES, UNITED STATES—ALASKA—NORTH

SLOPE.

The level of a lake supplying water to the LiZ-3 Dew Line Station, near the Chukchi Sea coast of Alaska, had fallen about a quarter of a meter. This lowering reduced the availability of water to the station during the winter and raised concern that the lake may continue to drain. A radar subsurface sounding survey of the lake was made in May 1984 to determine if the lake contained a deep area from which potable water could be drawn from under the ice during the winter. No acceptable deep areas were found. Recommendations are provided for preventing further drainage of the lake and for deepening a portion of the lake. A possible solution for making the sour water remaining under the winter lake ice acceptable for consumption is also presented.

ANCE, FATIGUE (MATERIALS), BEARING STRENGTH, FREEZING INDEXES.

Soft grades of asphalt cement are being used for controlling low temperature cracking in some parts of the northern regions of the United States and in Canada. The U.S. Army Corps of Engineers (COE) specified softer asphalts for use in cold regions (ETL 1110-3-369) dated Nov. 1976; at present, the COE uses the penetration viscosity number (PVN) as a measure of the temperature susceptibility of the asphalt. A minimum PVN of -05 is specified for moderately cold areas and -0.2 in regions where the design freezing index is greater than 39900 Chr. Field studies have been conducted that clearly show the benefits of using softer grades of asphalt for minimizing low temperature cracking in cold regions; however, field studies relating ruting to asphalt type are rare. A major concern is whether or not pavements constructed with softer grades of asphalt are more susceptible to rutting during the hot summer months. A field study was conducted by CRREL to gather information on the use of soft grades of asphalt (AC 25, AC 5 and AC 10) and their associated pavement performance. An attempt was made to compare the COE specifications with State DOT specifications for these soft grades of asphalt. The influence of the asphalts studied, and the preliminary results of this filed program, are presented in this report. For the longer term objectives of this study, new or reconstructed pavements in various parts of the country will be monitored for both low temperature cracking and rutting.

COMPARISON OF FOUR VOLATILE ORGANIC COMPOUNDS IN FROZEN AND UNFROZEN SILT.

MAFROST BENEATH ROADS, UNITED STATES—ALASKA—FORT WAINWRIGHT.

A thermal infrared imaging system was mounted on an Army UH-1H helicopter and used to conduct a series of survey flights over the winter. rail network of the Ft. Wainwright Training Area during November 1986. The training area is south of the Tanana River from Fairbanks and consists of 2600 sq. km. of neatly flat land underlain by discontinuous permafrost. A network of trails has been developed over the years to allow access to the training area during the winter for unit training and large-scale military maneuvers. The purpose of the survey flights was to try to identify areas along the trails where groundwater comes to the surface as springs, seeps and stream overflows. During the winter these outflow areas can be a source of extensive ground icings as the water repeatedly seeps to the surface and freezes. These areas frequently remain unfrozen below a thin see cover well into the winter, and vehicles have become stuck when they broke through the thrn ice. On the thermal IR imagery, overflow or icing areas were easily discernible as brighter (warmer) areas against the darker (colder) snow-covered terrain. Even at night, details of the snow-covered trails, siffields and different vegetation types could be ascertained in the thermal IR image, due to slight differences in thermal properties. Information acquired during this study was supplied to the Ft. Wainwright Directorate of Plans, Training, and Mobilization and was used to reroute trails around the overflow and icing areas, allowing unimpeded winter access into the training area.

MONOGRAPHS

THERMAL PROPERTIES OF SOILS.

Farouki, O.T., Dec. 1981, 136p., ADA-111 734, Refs. p.125-132. 30.1258

FROZEN GROUND THERMODYNAMICS, PER-MAFROST HEAT TRANSFER, FROZEN GROUND MECHANICS, SOIL PHYSICS, SOIL MECHANICS, THERMAL CONDUCTIVITY, SOIL WATER, SOIL FREEZING.

This monograph describes the thermal properties of soils, unfrozen or frozen. The effects on these properties of water and its phase changes are detailed. An explanation is given of the interaction between mosture and heat transfer. Other influences on soil thermal properties are described, necluding such factors as soil composition, structure, additives, salts, organics, hysteresis and temperature Techniques increasing such factors as soil composition, structure, additives, salts, organics, hysteresis and temperature. Techniques for testing soil thermal conductivity are outlined and the methods for calculating this property are described. The monograph gives the results of an evaluation of these methods whereby their predictions were compared with measured values, thus showing their applicability to various soil types and conditions.

M 81-02 FROST SUSCEPTIBILITY OF SOIL; REVIEW OF INDEX TESTS.

Chamberlain, E.J., Dec. 1981, 110p., ADA-111 752, For another source see 37-973 (MP 1557). Refs. p.83-88. 39-2034

39-2034 FROST HEAVE, SOIL FREEZING, SOIL ME-CHANICS, ICE WATER INTERFACE, ICE SOLID INTERFACE, SOIL CLASSIFICATION, TEM-PERATURE GRADIENTS, SOIL WATER, PARTI-CLE SIZE DISTRIBUTION, GRAIN SIZE.

CLE SIZE DISTRIBUTION, GRAIN SIZE.

Methods of determining the frost susceptibility of soils are identified and presented in this report. More than one hundred criteria were found, the most common based on particle size characteristics. These particle size criteria are frequently augmented by information such as grain size distribution, uniformity coefficients and Alterberg limits. Information on permeability, mineralogy and soil classification has also been used. More complex methods requiring pore size distribution, moisture-tension, hydraulic-conductivity, heave-streas, and frost-heave tests have also been proposed. However, none has proven to be the universal test for determining the frost susceptibility of soils. Based on this survey, four methods are proposed for further study. They are the U.S. Army Corps of Engineers Frost Susceptibility Classification System, the moisture-tension hydraulic-conductivity test, a new frost-heave test, and the CBR-after-thaw test

GROWTH, STRUCTURE, AND PROPERTIES OF SEA ICE.

Weeks, W.F., et al, Nov. 1982, 130p., ADA-123 762, Refs. p.117-130.

Ackley, S.F. 37-2407

SEA ICE, ICE ELECTRICAL PROPERTIES, ICE MECHANICS, ICE SALINITY, ICE THERMAL PROPERTIES, ICE CRYSTAL STRUCTURE, ICE PHYSICS, GRAIN SIZE, ICE CRYSTAL GROWTH, GAS INCLUSIONS, TEMPERATURE

This monograph describes in some detail the current state of knowledge of the observed variations in the structural characteristics (grain size, crystal orientation, brine layer spacing) and composition (brine, gas and solid salts) of sea ice as well as the presumed causes of these variations. The importance of these variations in controlling the large observed changes in the mechanical, thermal and electrical properties of the sea ice is also discussed.

MECHANICAL BEHAVIOR OF SEA ICE. Mellor, M, June 1983, 105p, ADA-131 852, Refs p.99-105. 38-469

SEA ICE, ICE MECHANICS, ICE ELASTICITY, ICE STRENGTH, FRACTURING, FLEXURAL STRENGTH, STRESSES, STRAINS, RHEOLOGY, MECHANICAL PROPERTIES, PRESSURE MECHANICAL PROPERTIES, PR RIDGES, ANALYSIS (MATHEMATICS).

The first part of the report provides an introduction to the mechanics of deformable solids, covering the basic ideas of stress and stream, rheology, equilibrium equations, strain/displacement relations, constitutive equations, and failure entreast Fracture mechanics and fracture toughness are also reviewed briefly. The second part of the report summarizes available data on the mechanical properties of freshwater ice and saline ice, accounting for the influences of strain rate and

loading rate, temperature, porosity, salinity, and grain size Boundary value problems are not dealt with, but there is discussion of some miscellaneous topics, including thermal strains, behavior of brash ice, and pressure ridges. The report was written as a study text for a NATO Advanced Study Institute on Sea/Ice/Air Interactions, and was intended to be used in conjunction with companion texts on related tonics.

M 84-01 FRAZIL ICE DYNAMICS.

Daly, S.F., Apr. 1984, 46p., ADA-142 037, Refs. p.44-

FRAZIL ICE, ICE MECHANICS, ICE CRYSTAL GROWTH, ICE CRYSTAL NUCLEI, HEAT TRANSFER, ICE FORMATION, ICE PREVENTION, SUPERCOOLING, TURBULENT FLOW, ANALYSIS (MATHEMATICS).

ANALYSIS (MATHEMATICS).

To describe the dynamic evolution of frazil ice in turbulent natural water bodies, the basic equation for dynamic frazil crystal number continuity and the basic equation of heat balance for a differential volume are developed. Crystal growth and nucleation of new crystals are the major parameters in these equations Expressions for the growth rate of frazil ice crystals are described. The growth rate along the major axis is controlled by heat transfer. The heat transfer coefficient is a function of crystal size, the fluid urbulence, and the fluid properties. The magnitude of inertial and buoyancy forces on the ice crystals are determined as is their influence on the heat transfer. Spontaneous nucleation of ice can be discounted; secondary nucleation is responsible for the vast majority of frazil ice crystals. The theoretical rate of secondary nucleation is partially modeled as a function of the supercooling, fluid turbulence and crystal size distribution. A simple analytical solution of the basic equations is developed for the growth of frazil ice in a well-mixed, steady-state crystalilizer.

ATMOSPHERIC ICING ON SEA STRUCTURES. Makkonen, L., Apr. 1934, 92p, ADA-144 448, Refs.

ICING, OFFSHORE STRUCTURES, ICE ACCRE-ICING, OFFSHORE STRUCTURES, ICE ACCRETION, ICE PREVENTION, ICE ADHESION, ICE SOLID INTERFACE, ICE PHYSICS, CLIMATIC FACTORS, ICE LOADS, SUPERCOOLING, ANALYSIS (MATHEMATICS), DESIGN.

ANALYSIS (MATHEMATICS), DESIGN.
Atmospheric icing (icing due to fog, precipitation and watervapor in air) as a physical process and the problems it causes for ships and stationary offshore structures are reviewed Estimation of the probability and seventy of atmospheric icing based on climatological and geographical factors is discussed, and theoretical methods for calculating the intensity of atmospheric icing at sea are suggested. Ensisting data on the dependence of the atmospheric icing rate and the properties of the accreted ice on the meteorological conditions are analyzed. The methods of measuring the icing rate and ice prevention methods are discussed.

M 84-03

Hibler, W.D., III, July 1984, 52p., ADA-147 376, Refs. p.48-52. 39-896

ICE MECHANICS, RHEOLOGY, DRIFT, THER-MODYNAMICS, ICE PLASTICITY, OCEANOG-RAPHY, SEA ICE, ICE FORMATION, ICE 'AIR INTERFACE, ICE WATER INTERFACE, ICE STRENGTH, ICE COVER THICKNESS, ICE MODELS, SEA WATER, ANTARCTI' A—WED-

DELL SEA.

This monograph reviews essential aspects of sea ice dynamics of the Arctic and Antarctic on the geophysical scale and discusses the role of ice dynamics in air-sea-ice interaction. The review is divided into the following components a) a discussion of the momentum balance describing ice drift, b) an examination of the nature of sea ice rheology on the geophysical scale, c) an analysis of the relationship between ice strength and ice thickness characteristics, and d) a discussion of the role of ice dynamics in the atmosphere-coccan system

Because of the unique, highly nonlinear nature of sea-ice interaction, special attention is given to the ramifications of ice interaction on sea ice motion and deformation

These ramifications are illustrated both by analytic solution and by numerical model results. In addition, the role of ice dynamics in the atmosphere-ice-occan system is succussed in light of numerical modeling experiments, including a fully coupled ice-occan model of the Arctic-Greenland-Norwegian seas

M 85-01 EROSION OF NORTHERN RESERVOIR SHORES. AN ANALYSIS AND APPLICATION

OF PERTINENT LITERATURE.

Lawson, D.E., May 1985, 198p., ADA-157 811, Refs.

SHORE EROSION, ICE COVER EFFECT, RESERVOIRS, SLOPE PROCESSES, PERMAFROST, SHORELINE MODIFICATION, GROUND WA-TER, WATER LEVEL, MODELS, WATER WAVES, FORECASTING, TEMPERATURE EF-

FECTS.

This monograph describes the current state of knowledge of northern reservoir shore crosson, primarily by examining the results of crossonal studies on lakes, coasts and rivers. The major crossonal processes of reservoir beaches and bluffs and their mechanics are discussed in detail. Thermal and physical parameters affecting the crodibility of shores, the environmental impacts of crosson, and the basic characteristics of the unique reservoir environment are reviewed. Current models of shore zone development are also presented. This interature analysis revealed that knowledge of crosson and recession in northern impoundments is severely limited. Quantitative analyses of the processes of crosson and their relative importance, parameters determining the nature, rate relative importance, parameters determining the nature, rate and timing of erosion, and models to predict the erodibility of a shore for use in minimizing shoreline recession remain in need of basic field research.

M 88-01

HEAT CONDUCTION WITH FREEZING OR

THAWING. Lunardini, V J., Apr. 1988, 329p., Refs. p.267-281. 43-3847

HEAT TRANSFER, PHASE TRANSFORMA-TIONS, CONDUCTION, FREEZING, MELTING,

Freezing of water or melting of see are phenomena that underhe many important scientific and engineering studies of cold regions. Mathematical methods of treating these phase-change heat transfer problems are critical to understanding and dealing with the problems that freeze-thaw causes. While convection may be an important heat transfer mode, it can often be neglected without significant error. This treport deals only with problems for which conduction is the basic heat transfer mode or for which the solutions can be obtained in terms of conductionalities problems. the basic heat transfer mode or for which the solutions can be obtained in terms of conduction-like problems, where possible, exact solutions are presented, but since these are quite limited for phase-change problems, approximate solutions are examined in some detail. The approximate methods are 1) the perturbation method, which leads to quasi-stationary techniques, 2) the heat balance integral method, and 3) Biod's variational principle. The theory associated with these methods is discussed in the appendixes. The available exact solutions are derived and explained. Graphical solutions are then developed for practical applications or widely occurring problems. The approximate solutions are used to generate design curves—such as those for phase-change depth, temperature, and heat flow vs time. The results are presented so as to be easily accessible to practicing engineers without recourse to claborate calculations. This is especially true for application to soil systems is especially true for application to soil systems

SEA ICE DISTRIBUTION, ICE PHYSICS, ICE DEFORMATION, ICE CONDITIONS, CLIMATIC FACTORS, ICE MECHANICS, MEETINGS.

The W.F. Weeks Sea Ice Symposium held in San Francisco, Dec 1988 includes 84 papers and abstracts written by about 150 authors Studies of sea ice properties carried out in the Arctic and Antarctic were reported

CHARACTERISTICS OF THE COLD REGIONS. Gerdel, R.W., Aug. 1969, 51p., AD-695 661, 64 refs.

TEMPERATURE DISTRIBUTION, SNOW COVER DISTRIBUTION, GLACIER ICE, FROZEN GROUND, PERMAFROST STRUCTURE, EN GROUND, PERMAFROST LAKE ICE, RIVFR ICE, SEA ICE.

The paper gives a brief introduction to total cold environments relating the chara-teristics of the cold regions to the problems

produced which hinder man's activities in these regions Discussed are the zonal temperature regimes, the various forms and aspects of snow and ice, frozen ground and permatrost and the atmospheric phenomena of the greenhouse effect, refraction, reflection, and luminance.

SELECTED ASPECTS OF GEOLOGY AND PHYSIOGRAPHY OF THE COLD REGIONS. Stearns, S.R., July 1965, 40p., AD-630 983, 50 refs. 24-3399

STRUCTURES, MOUNTAINS, DISTRIBUTION, PERMA. GEOLOGIC MOUNTAINS, PLAINS, TEMPERATURE DISTRIBUTION, TOPOGRAPHIC FEATURES, SEA ICE, PERMA-FROST.

The cold regions of the earth are defined and described in terms of their physiographic features geologic histories, temperature characteristics, vegetation limitations, permafrost

PERMAPROST (PERENNIALLY FROZEN GROUND).

Stearns, S.R., Aug 1966, 77p., AD-642 730, Includes, p.71-77, Description and classification of frozen soils by K.A. Linell and C.W. Kaplar Bibliog.

Linell, K.A., Kaplar, C.W.

PERMAFROST DISTRIBUTION, PERMAFROST STRUCTURE, PERMAFROST HEAT BALANCE SURFACE FEATURES, VEGETATION PAT TERNS, COLD WEATHER CONSTRUCTION.

This monograph summarizes information on permafrost for engineering construction in cold regions The distribution and origin of permafrost is discussed and information on structure, thickness, and thermal regime is summarized. Patterned ground and vegetation in the cold regions are discussed and the engineering significance of permafrost is reviewed

M I-A3a CLIMATOLOGY OF THE COLD REGIONS. INTRODUCTION. NORTHERN HEMISPHERE, PART I.

June 1967, 141p., AD-656 447, For Part II See 24-3402, 323 refs

CLIMATOLOGY, TOPOGRAPHIC FEATURES, ATMOSPHERIC CIRCULATION, HEAT BALANCE, RADIATION BALANCE.

ANCE, RADIATION BALANCE.

A review summary of the climatological environment of the Northern Hemisphere contains a general introduction to the cold regions and a discussion of geographic controls and meteorological aspects including 1) the hemisphere surface in terms of configuration and relief, vegetation zones and permanent and seasonal ice and snow, 2) the general circulation and weather system dealing with the circumpolar vortex, sea-level pressure and cyclomic frequency, circulation system persistence, and surface weather associated with high latitude pressures. 3) the net radiation and heat halance pressures. 3) the net radiation and heat balance

M T-A3h CLIMATOLOGY OF THE COLD REGIONS NORTHERN HEMISPHERE. PART II. Wilson, C., Aug. 1969, 158p., AD-674 185, For Part I, see 24-3401. Extensive bibliogs with each major

24-3402

CLIMATOLOGY, TEMPERATURE EFFECTS, HUMIDITY, PRECIPITATION (METEOROLOGY), WIND FACTORS, ICE FOG.

Three major topics are treated in this paper humidity and precipitation, and surface winds Temperature, and inversions are presented Visibility and icing data are included with the section on atmospheric humidity and precipitation. Average and maximum wind speeds with the prevailing directions and blowing snow data are given

M I-A3c CLIMATOLOGY OF THE COLD REGIONS SOUTHERN HEMISPHERE.

Wilson, C., May 1968, 77p., AD-674 185, 281 rcfs

CLIMATOLOGY, ATMOSPHERIC CIRCULA-TION, HEAT BALANCE, METEOROLOGICAL DATA, ANTARCTICA.

DAIA, ANT INCLUENT.

This monograph summarizes the climatology of the cold regions of the Southern Hemisphere which consist almost entirely of the Antarctic Continent Comparisons with the northern cold regions are followed by a systematic treatment of general circulation, the energy budget, and menectrological elements forming the climate of the region. Thirty-two illustrations (many of several parts) and ten tables give climatological data, and a selected bibliography of 281 items provides complete coverage for further details.

M I-A3d RADIOACTIVE FALLOUT IN NORTHERN RE-

Wilson, C., Feb 1967, 35p. AD-656 448, 119 refs 24-3404

FALLOUT, RADIOACTIVE ISOTOPES, ATMO-SPHERIC CIRCULATION.

Information and data are given on the distribution of radioac-Information and data are given on the distribution of radioactive fallout and atmospheric processes, announced nuclear detonations, and monthly fallout deposition collection. It is pointed out that the 3 dangerous isotopes are Sr-90, Cs-137, and I-131. The data suggest that the arctic and subarctic stratorsphere plays an important role in the retention and release of 142 outcive fallout so that, regardless of the latitude at which the debris is injected into the stratosphere he fallout pattern may be unchanged. There is a close relationship between the troposphere jet streams and associated cyclonic disturbances and the distribution of fallout at the earth's surface. This hypothesis calls for the transfer of the debris in well-defined layers from the arctic stratosphere deep down into the troposphere in the vicinity of the ret of the deoris in well-defined layers from the arctic stratosphere deep down into the troposphere in the vicinity of the jet stream, where subsidence in the rear of cyclonic disturbances and the precipitation processes aid the rapid fall to earth. In the northern regions, fallout behavior depends on the initial pattern of the westerly vortex at the time of the detonation and its subsequent development

M I-B1 ANTARCTIC ICE SHEET.

Mellor, M., Feb. 1961, 50p., AD-276 609, 65 refs. 24-3405

LAND ICE, ICE COVER THICKNESS, ICE TEM-PERATURE, SNOW COVER, MASS BUDGET, ANTARCTICA.

ANIANCIICA.

The paper summarizes existing (as of 1960) knowledge of the Antarctic continent for the use of professional engineers engaged in design or construction in that region. Treated are the topographic features, accumulation, ablation, and drifting of snow, and a variety of ice characteristics including flow, thickness, variation of properties, temperature, mass budget, and annual gains and losses.

M I-B2 GREENLAND ICE SHEET.

Bader, H., Sept. 1961, 18p, AD-276 610, 11 refs.

LAND ICE, ICE COVER THICKNESS, ICE TEM-PERATURE, SNOW DENSITY, FIRNIFICATION. The paper summarizes the existing (as of 1961) knowledge of Greenland for use of professional engineers engaged in design or construction in that region. Discussed are the extent and thickness of the ice sheet, the regimen under which it exists, surface and subsurface temperatures, and snow densification

M II-A1 HEAT EXCHANGE AT THE GROUND SUR-

Scott, R.F., July 1964, 49p. plus append, AD-449 434, 56 refs

MEASURING INSTRUMENTS, METEOROLOG-ICAL DATA, WIND FACTORS, TEMPERATURE EFFECTS, SOIL TEMPERATURE, HEAT BAL-ANCE, FREEZE THAW INDEXES

The parer summarizes existing (as of 1964) knowledge of heat exchange at the ground surface from an engineering viewpoint, aiming at the solution of the problem of predicting the ground penetration of the freezing point isotherm from meanur, son, and surface conditions. As perameters used in the solution, radiation, wind and air temperature, soil and subsurface transperatures, surface heat balance, and freezing and thawing indexes are considered. weather, soil, and surface conditions As perameters used

M II-32a

SEISMIC EXPLORATION IN COLD REGIONS. Roethlisberger, H. Oct 1972, 138p, AD-752 111, 199 rcfs

27-1681

SUBSURFACE INVESTIGATIONS, SEISMIC VELOCITY, ICE PLASTICITY, SNOW PLASTICITY, FROZEN GROUND MECHANICS, GLA-CIERS.

CIERS.

This monograph contains a comprehensive review of the use of seismic methods and related techniques based on elastic waves, to gain information on the geometry and physical properties of the substrata in cold regions, particularly snow, ice and frozen ground Pettinent elastic properties of these materials are described and methods for determining seismic velocities are summarized Theories and application of reflection and refraction soundings on glaciers, continental ice sheets, ice shelves, and frozen ground are reviewed Surveys employing surface waves, and application included with the text are 73 figures and about 200 selected references

M II-B PHYSICS AND MECHANICS OF SNOW AS A MATERIAL.

Bader, H., et al. July 1962, 79p., AD-287 052, 60 refs. Kuroiwa, D

SNOW PHYSICS, ELECTRICAL PROPERTIES, THERMAL PROPERTIES, METAMORPHISM (SNOW), CLASSIFICATIONS, SNOW DENSITY. SNOW COMPRESSION, COMPRESSIVE STRENGTH, SNOW CREEP, TENSILE TENSILE STRENGTH, SHEAR STRENGTH

The paper summarizes existing (as of 1962) knowledge of the properties of snow as a material — Its structure, changes, permeability, classification, mechanics, thermal and electrical properties are described and illustrated

M II-C1

SNOW AND ICE ON THE EARTH'S SURFACE. Mellor, M., July 1964, 163p., AD-449 925, Chapter bibliographies. 24-3409

SNOW PHYSICS, GLACIER ICE, GLACIOLOGY, ICE FORMS

An extensive treatment is given to the various aspects of glaciers including classification, area and thickness, and distribution; flow, wastage, mass economy, temperatures, past glaciations, and study techniques

The natural forms of ice, tions, and study techniques The natural forms of ice, ie, snow, frost, lake ice, river ice, sea ice, icebergs, and ground ice are described Snow is treated from the viewpoint of its effects and changes after it has fallen to the surface.

M II-C2a

PHYSICS OF ICE.

Glen, J.W., April 1974, 81p., AD-778 009. 28-4125

ICE PHYSICS, ICE CRYSTAL STRUCTURE, ICE MELTING, ICE SURFACE.

Existing knowledge of ice physics is summarized lee crystalline structure including defects in structure, polycrystalline ice and grain boundaries, electrical properties, thermal properties, propagation of electromagnetic waves in ice and optical properties, nucleation and growth of ice crystals, melting and evaporation, and surface properties are covered A comprehensive bibliography is given.

M II-C2b

MECHANICS OF ICE. Glen, J.W., Dec. 1975, 43p, ADA-022 797, 134 refs.

MECHANICS, ICE ELASTICITY, ICE EP, PLASTIC DEFORMATION, BIBLIO-GRAPHIES.

This monograph summarizes knowledge of the mechanics of ice to 1970. It is concerned principally with the effect of stress on the nicchanical properties of ice, including clasticity, anelasticity, sound propagation, plastic deformation and creep in single crystals and in polycrystalline ice, fracture, and recrystallization and grain growth that accompanies plastic deformation. The monograph also includes a comprehensive bublicoreably.

M II-C3 MECHANICAL PROPERTIES OF SEA ICE.

Weeks, W.F, et al, Sept. 1967, 80p., AD-662 716, 199 refs.

Assur. 24-3410

SEA ICE, ICE COVER STRENGTH, TENSILE STRENGTH, FLEXURAL STRENGTH, SHEAR STRENGTH, COMPRESSIVE STRENGTH, ICE CREEP, MECHANICAL PROPERTIES

CREEP, MECHANICAL PROPERTIES

This review discusses the state of thinking of each of the main national groups investigating see ice and gives an overall appraisal of the field as a whole Emphasis is placed on (1) the physical basis for interpreting sea i.e strength (phase relations, air volume, and structural considerations), (2) theoretical considerations (strength modela, air bubbles and salt reinforcement, and interrelations between growth conditions and strength), (3) experimental results (tensile, flexural, shear, and compressive strength, elastic modulus, shear modulus and Poisson's ratio, time dependent effects, and creep), and (4) plate characteristics. The paper includes a review of problems in we are investigations, relates the chemical, crystallographic, mechanical, and physical aspects involved, and concludes by showing how to utilize this knowledge to solve practical problems

FREEZING PROCESS AND MECHANICS OF FROZEN GROUND.

Scott, R.F., Oct 1969, 65p., AD-697 136, 64 refs 24-3411

FROZEN GROUND MECHANICS, FREEZING, FROST ACTION, VISCOELASTICITY, SOIL STRENGTH.

Outlined are two current theories on the freezing of water in soils. The classification and description, standardized in the United States and Canada, of frozen soils, leads to some laboratory data on the incehanical behavior of frozen soils. The Monograph concludes with the application of linear viscoelastic theory to typical field problems. Twenty-one illustrations, 7 tables and 64 references are included

PROPERTIES OF SNOW.

Mellor, M., Dec. 1964, 105p., AD-611 023, Chapter

24-3412 SNOW PHYSICS, SNOW STRENGTH, LOADS (FORCES), SHEAR STRENGTH, SNOW CREEP, THERMAL PROPERTIES, ELECTRICAL PROP-ERTIES.

The paper summarizes existing (as of 1964) knowledge of the properties of snow Snow structure and structural changes are discussed as products of variations in grain size, porosity, density and as the result of loading variations which affect the ultimate strength and ereop of snow Emplayized after are waste in which have a transformatic terms. phasized also are ways in which heat is transferred through snow and the changes which result

M III-A2a METHODS OF BUILDING ON PERMANENT SNOWFIELDS.

Mellor, M., Oct. 1968, 43p., AD-681 889, 14 refs. 24-3413

24-3413
COLD WEATHER CONSTRUCTION, SNOW (CONSTRUCTION MATERIAL), UNDERSNOW FACILITIES, ANTARCTICA, GREENLAND.
Construction on the polar ice sheets of Greenland and Antarctication of the polar ice sheets of the polar ice sheets of the polar ice sheets of

tica is a challenge, mainly because of the mechanical and thermal sensitivity of snow, the major constructional material. Adverse weather, logistical difficulties, and lack of experience Adverse weather, logistical difficulties, and lack of experence add to the problem to make every project a costly experiment. This monograph describes the development of building in, on, and of, snow, beginning with the Eskimo snowhouse for temporary shelter, and leading to permanent installations like 6500-ton steel structures above the snow surface, and a large subsurface encampment maintained with the help of a nuclear reactor. The work is introductory to other monographs dealing with specific aspects of design, construction and operation.

M III-A2b

INVESTIGATION AND EXPLOITATION OF SNOWFIELD SITES.

Mellor, M., Jan. 1969, 57p., AD-686 314, 32 refs.

24-3414 COLD WEATHER CONSTRUCTION, SNOW (CONSTRUCTION MATERIAL), UNDERSNOW FACILITIES, MEASURING INSTRUMENTS, FACILITIES, MEASURING INST SNOW STRENGTH, EXCAVATION.

This monograph is the 2nd of a series of 5 It covers the site investigations and laboratory tests in connection with construction on a permanent snowfield, and then deals with the technology of excavation and building where snow is almost the only constructional maternal The author draws heavily on the work of the Cold Regions Research and Engineering Laboratory (CRREL) in the development of Camp Century and other projects on the Greenland ice sheet and shows the application of the techniques to Antarctic Research Stations.

FOUNDATIONS AND SUBSURFACE STRUC-TURES IN SNOW.

Mellor, M., Oct. 1969, 54p., AD-699 336, 31 refs.

FOUNDATIONS, SNOW PHYSICS, SNOW (CON-STRUCTION SUBSURFACE MATERIAL), STRUCTURES.

Various types of foundations suitable for use in very deep snow are described, and design principles are given Dependence of settlement rate on heaving pressure, size and shape of foundation, snow temperature, and snow density is treated analytically, and field data from test procedures for foundation analytically, and field data from test procedures for foundation design are outlined. In treating the design of tunnels, shafts and subsurface structures in very deep snow, the distributions of stress, strain and displacement in polar ice sheets are first obtained analytically. Observed patterns of deformation are given for a variety of excavations and deformable structures, and methods of analysis are put forward. The loading of rettraining structures is discussed, and finally some notes on the monitoring and maintenance of subsurface structures are size. structures are given

M III-A2d

UTILITIES ON PERMANENT SNOWFIELDS. Mellor, M., Oct. 1969, 42p., AD-699 337, 46 1cfs.

COLD WEATHER CONSTRUCTION, WATER SUPPLY, WASTE DISPOSAL, UTILITIES, FIRES, HEATING, VENTILATION.

HEATING, VENTILATION.

The topics covered in the monograph include water supply, waste disposal, heating, ventilating and fire protection at installations built on polar ice sheets. The section on water supply discusses energy requirements, consumption rates, water quality and treatment, techniques and equipment for melting snow and ice, and water distribution systems. A number of actual water supply systems are described in detail. The section on waste disposal deals with sewage and sewage sinks, latrines, garbage, trash and scrap and radioactive waste. Examples of sanitation systems at polar base are described in some detail. The section on heating discusses heating load, heat losses and insulation, energy sources, and heating systems. The ventilation section covers air demands, intakes and exhausts, ventilation of undersnow tunnels, and carbon monoxide problems. The report concludes with some notes on fire protection.

M III-A3a

EXPLOSIONS AND SNOW.

Mellor, M., June 1965, 34p., AD-623 418, 23 refs. 24-3415

EXPLOSION EFFECTS EXPLOSION EFFECTS, ATTENUATION, SHOCK WAVES, SNOW MECHANICS.

Described are experiments with blasting in snow of the charge and the depth placed are related to the size and configuration of the resulting crater and the permanent deformation of the snow. Shockwaves in the snow and in the air are discussed and engineering applications of snow blasting are indicated

M III-A3b SNOW REMOVAL AND ICE CONTROL. Mellor, M., April 1965, 37p., AD-615 795, 32 refs.

SNOW REMOVAL, ICE CONTROL

Climatology of snow cover in the northern hemisphere is briefly presented along with a description of significant snow properties. More extensively treated are the various equipments and methods used to control ice and snow. Snow plows, and methods used to control uce and snow. Snow plows, heating systems, and chemical means of snow removal are compared and details of costs and organization of removal techniques are presented

M III-A3c BLOWING SNOW.

Mellor, M., Nov. 1965, 79p., AD-630 328, 97 refs.

SNOWDRIFTS, BLOWING SNOW, WIND FACTORS, SNOW FENCES, TURBULENT DIFFU-

The monograph reviews available information on blowing The monograph reviews available information on blowing snow and the formation of snowdrifts. The mechanics of wind transport is discussed, with special emphasis on turbulent diffusion of snow particles in the surface boundary layer. The metering of blowing snow is explained, and field data are given for concentration and flux of snow particles as functions of wind speed and height above the surface. Deposition and erosion of snow is discussed and wind tunnel modeling is considered. The construction and deployment of snow fences is described, and snow fence. wind tunnel modeling is considered. The construction and deployment of snow fences is described, and snow fence performance is analysed. Snow drifting on highways and around structures is considered. Some electrical and optical phenomena are reviewed

M III-A3d

AVALANCHES.

Mellor, M., May 1968, 215p., AD-671 614, 134 refs. 24-3418

AVALANCHES, AVALANCHE COUNTER-MEASURES, AVALANCHE MECHANICS, AVA-LANCHE TRIGGERING, SLOPE STABILITY.

This monograph contains a comprehensive review of the formation and occurrence of avalanches together with a technical treatment of the principles and practice of avalanche defense. Major sections deal with avalanche hazard, snow-fall and snow cover, avalanche terrain, avalanche classification, tail and show cover, avalanche terrain, avalanche classification, stress and deformation in snow slopes, engineering mechanics, avalanche dynamics, avalanche defenses, design of supporting structures and galleries, avalanche triggering and slope stabilization, probability forecasting, warning and rescue, and ice avalanches. A glossary of avalanche terminology in English, German and French is given in an appendix

M III-A4

OVERSNOW TRANSPORT.

Mellor, M., Jan. 1963, 58p. plus appends., AD-404 778, 32 refs. 24-3419

VEHICLES, CREVASSE DETECTION. DESIGN CRIT_RIA.

Snow vehicles of various types are described and illustrated Use, capabilities, limitations, and design features are presented and the procedures used to test the vehicles are given. Characteristics of good oversnow vehicles in terms of speed, power, load capacity, flotation, and traction are described M III-Bla

WINTER REGIME OF RIVERS AND LAKES. Michel, B., April 1971, 131p., AD-724 121, 164 refs

LAKE ICE. RIVER ICE, ICE SURVEYS, ICE FOR-MATION, HEAT BALANCE, FRAZIL ICE, ICE BREAKUP, ICE CONTROL, ICE FORECASTING. The monographs summarizes existing knowledge of river and lake ice surveys, heat balance on open water in winter, frazil, ice cover formation, ice breakup and ice control M III-BIb

PRESSURE ON ENGINEERING STRUC-TURES.

Michel, B., June 1970, 71p., AD-709 625, 79 refs.

ICE PRESSURE, STRUCTURES, ICEBREAKERS, ICE BREAKING, STATIC LOADS, DYNAMIC LOADS

This monograph summarizes existing knowledge on forces exerted by an expanding ice sheet, impact forces of ice on structures, and vertical forces exerted by ice on hydraulic structures

Sections are also devoted to icebreakers and ice models

M III-C4

FOUNDATIONS OF STRUCTURES IN COLD REGIONS.

Sanger, F.J., June 1969, 91p., AD-694 371, 62 reis. 24-3420

COLD WEATHER CONSTRUCTION, FOUNDA-TIONS, FROST HEAVE, PERMAFROST ERVATION, SEASONAL FREEZE THAW.

This monograph describes the various kinds of foundations used for structures on permafrost with a brief discussion of foundations in areas of seasonal frost. Special attention is given to piled foundations in permafrost and the design of ventilation systems for controlling that under heated buildings. Appendixes outline techniques for computing the depth of freezing or of thawing, the design of refrigeration systems for artificial freezing, and the recommended procedure in the USSR for static pile tests. Included in the main text are 51 figures and 62 selected references

M III-C5a

WATER SUPPLY IN COLD REGIONS. Alter, A.J., Jan. 1969, 85p, AD-685 850, 228 refs.

24-3421

COLD WEATHER OPERATION, WATER SUP-PLY, WATER TREATMENT.

The monograph outlines the influence of a cold environment on sanitary engineering works and services. It then deals with water supply in cold regions sources, distribution systems, treatment processes and possible future supply from other than geological sources.

M III.CSh

SEWERAGE AND SEWAGE DISPOSAL IN COLD REGIONS.

Alter, AJ, Oct. 1969, 106p., AD-698 452, 225 refs.

SEWAGE DISPOSAL, SEWAGE TREATMENT, UTILITIES, WASTE DISPOSAL, COLD WEATHER OPERATION.

ER OPERATION.

The main items dealt with in this monograph are practice and problems encountered by the builder and operator of sewerage works facilities in cold regions, collection and transport systems; treatment and processing of sewage, thermology, reuse and regenerative processes for treating waste water, and construction and operation of sewage facilities. Six appendixes treat stabilization ponds, venetilation of buildings having sewage treatment plant, management of solid waste and classification of wastes and incinerators.

M III-D3

ICINGS DEVELOPED FROM SURFACE WATER AND GROUND WATER

Carey, K L., May 1973, 71p. AD-765 452, 80 refs. 28-2877

ICE FORMATION, GROUND WATER, ICE CON-TROL, ENGINEERING.

TROL, ENGINEERING.

This monograph summanzes existing knowledge of the occurrence, control, and prevention of teings It covers brief history of icing studies, general descriptions of icings, engineering significance of icings, origins of icings and factors affecting icing formation, techniques for studying icings, techniques for counteracting icings, avoiding icing problems in new construction, and selected bibliography

A cold room has been constructed at the Frost Effects Laboratory, New England Division, Corps of Engineers, U S Army, for the purpose of conducting laboratory studies to determine the effect of various factors influencing ice segregation in soils and to study, in general, the frost phenomena in soils, with the objective of establishing design and evaluation criteria for roads, highways, and artifield runways constructed on frost susceptible soils which are subject to seasonal freezing

MP 843 ON THE USE OF TENSIOMETERS IN SNOW HYDROLOGY.

Colbeck, S.C., 1976, 17(75), p.135-140, 11 refs.

SNOW HYDROLOGY, MEASURING INSTRU-MENTS, WATER PRESSURE.

MENTS, WATER PRESSURE.

The construction and use of snow-water tensiometers is described. Water pressure at the base of a shallow, Arctic anow-pack was measured to illustrate the response of the basal layer to water percolation. Water tension above an ice layer and water flux through the ice layer were measured in glacial snow. The gravity flow theory is used to explain the close agreement between these parameters. This suggests that the ice layer has little effect on the flow field and that gravity (rather than tension gradients) controls the flow. Further work on water tensions is needed to identify the role of tension gradients in ripening and shallow snow covers. (Auth.)

BOREHOLE INSTRUMENTS, ICE SHEETS, FLOW MEASUREMENT, MECHANICAL PROP-ERTIES, ANTARCTICA-BYRD STATION.

ERTIES, ANTARCTICA—BYRD STATION.

The drill hole at "Byrd" station, which was completed in Jan 1968 to a vertical depth of 7063 ft (2153 m) below the top of the hole casing, was resurveyed in Jan 1975 to a vertical depth of 4835 ft (1474 m). Inclination and azimuth measurements were made with a Parsons multiple shot inclinometer and compared with the earlier measurements made duning drilling. The results indicate a progressively increasing displacement with depth to a value of 51.2 ft (15.6 m) or about 7.3 ft/year (223 m/year) at the 4835 ft (1474 m) level. The direction of movement relative to the surface varies from south-west at 300 ft (915 m) to north-east at 4835 ft (1474 m), indicative of a complex twisting motion. An increase in accessible depth along the hole axis of 18 ft (549 m) beyond the 1969 depth was noted. No attempt was made to incasure the hole diameter or vertical strain. It is recommended that the hole be resurveyed in 3-5 years if it is still logistically feasible, using a more up-dated inclinometer. (Auth)

MP 847 GAS INCLUSIONS IN THE ANTARCTIC ICE SHEET AND THEIR GLACIOLOGICAL SIGNIFICANCE.

ICE SHEETS, DRILL CORE ANALYSIS, GAS IN-CLUSIONS, BUBBLES, AIR ENTRAINMENT, ICE PRESSURE, ANTARCTICA—BYRD STA-

TION.

ICE PRESSURE, ANTARCTICA—BYRD STATION.

Cores obtained to the bottom of the Antarctic Ice Sheet
at Byrd Station have been used to analyze some physical
properties of the air bubbles trapped in the ice. These
bubbles constitute the remnant air that is retained when
polar snow transforms into glacial ice. Parameters measured
include size, shape, abundance, and spatial distribution of
bubbles, gas volumes, and bubble pressures and their veriations
with depth in the ice sheet. Bubbles occur abundantly
in the top 300 m of ice but their gradually disappear until
they can no longer be detected optically below 1100 m.
This disappearance is not accompanied by any significant
loss of air from the ice, and the available evidence suggests
that the air is retained in the form of a gas hydrate of
clathrate. Because of the release of confining pressures
following drilling, the hydrate begins to decompose soon
after cores are pulled to the surface. This decomposition
is accompanied by the growth of gas-filled bubbleike cavities
that are easily distinguishable from original air bubbles. Bubble pressure measurements show that (1) bubbles with pressures
exceeding abtivit 16 bars begin to relax back to this value
soon after in situ pressures are relieved by drilling. (2)
further slow decompression is controlled to some extent by
the intrinsic structural properties of the ice and its thermal
and deformational history. Only small variations were
observed in the entrapped air content of the ice cores;
they probably reflect variations in the temperature and/or
pressure of the air at the time of its entrapment. Only
in ice from the bottom 483 m was the air content observed
of air coincided precisely with the first appearance of stratified
moraine in the cores, it is concluded that this ice originated
from the refreezing of air-depleted water produced under
pressure melting conditions at the bottom of the ice sheet.

INGS

SEA ICE, PRESSURE RIDGES, AIR CUSHION VEHICLES, ICE CROSSINGS, HEIGHT FIND-

Sea ice pressure ridges are major obstacles to vehicle mobility in the Arctic Basin. An estimate of the expectation of holes of various heights and widths in the ridges is desirable for optimum vehicle design. This study uses probability theory and ridge shadow measurements from aerial photographs of sea ice to determine the distribution of holes of various heights and widths in pressure ridges. General conclusions are drawn regarding trafficability of this terrain for vehicles of various sizes. Sea ice pressure ridges are major obstacles to vehicle mobility

MEASUREMENT OF SEA ICF DRIFT FAR FROM SHORE USING LANDSAT AND AERIAL PHOTOGRAPHIC IMAGERY.

Hibler, W.D., III, et al. International Symposium on Ice Problems, 3rd, Hanover, New Hampshire, 18-21 August 1975 Proceedings, International Association of Hydraulic Research, 1975, p.541-554, 6 refs Tucker, W.B., Weeks, W.F. 30-2755

SEA ICE, AERIAL SURVEYS, PHOTOGRAMME-TRY, ICE DEFORMATION, DRIFT, LANDSAT

This paper discusses recent work on the development of analysis procedures for obtaining drift and deformation meaanalysis procedures for obtaining drift and deformation mea-sured from sequential visual imagery of sea rec that is located far from land. In particular for LANDSAT images far from land a semi automatic procedure for transferring the location coordinates of a common set of see features from the Earth coordinate system of one image to another is discussed. Necessary inputs for the transfer are the location coordinates (latitude and longitude) of the center of each image and the location of two arbitrary points on a known line of longitude, all this information is available from LAND SAT, although with some error. These errors will produce

spurious apparent strains if velocities are estimated by simply taking position differences. With regard to measuring strain from sea ice aenal imagery without ground control, errors in such measurements are examined using uncorrected photographs. The errors in using such uncorrected imagery and using common undeformed ice floes to establish a common scale are found to be of the order of 1% whereas typical maximum differential motions are as large as 5%.

STATISTICAL VARIATIONS IN ARCTIC SEA ICE RIDGING AND DEFORMATION RATES.

Hibler, V.D., III, Ice Tech Symposium, Montreal, Canada, April 9-11, 1975. Proceedings, New York, Society of Naval Architects and Marine Engineers, 1975, p.J1-J16, 13 refs Includes discussions 30-1846

SEA ICE, PACK ICE, ICE DEFORMATION, ICE PRESSURE, OFFSHORE STRUCTURES, ICE CONDITIONS, STRESSES, ICE NAVIGATION, STATISTICAL DATA.

STATISTICAL DATA.

Past studies of statistics of pressure ridges have supplied useful information on the nature of pressure ridge height and spacing distributions as well as information on geographical and temporal variations in ridging. These statistics should be of some aid in the construction of Arctic offshore structures and in Lebreaking and shipping operations. By coupling these height and spacing statistics with information on ridge lengths, the amount of detouring necessary to avoid ridges may be estimated. Closely associated with ridging are drift and deformation studies. Two aspects of these studies applicable to this conference are (1) the prediction of the rate of opening and closing of the pack ice, and (2) estimation of typical geophysical stresses in the ice pack.

Theoretical and experimental work at CRREL indicates that certail approximate rules may be invoked to estimate the divergence. and experimental work at CRREL indicates that certain approximate rules may be invoked to estimate the divergence rate far from coastal boundaries, namely that ir. winter the pack ice should diverge in reasonably well localized high pressure systems, whereas in summer the ice typically diverges in low pressure systems. As regards estimates of geophysical stresses, estimates from a variety of sources suggest that maximum atresses integrated through the pack ice thickness are of the order of 10,000 to 100,000 N/m. The upper limit is approximately equal to the force required to crush 0.25-meter-thick sea ice

CONTINUOUS MONITORING OF TOTAL DIS-SOLVED GASES, A FEASIBILITY STUDY.

IDENTIFICATION OF NUCLEI AND CONCEN-TRATIONS OF CHEMICAL SPECIES IN SNOW CRYSTALS SAMPLED AT THE SOUTH POLE. Kumai, M., May 1976, 33(5), p.833-841, 16 refs. 30-3647

SNOW COMPOSITION, CLAY MINERALS, SNOW CRYSTAL NUCLEI, ANTARCTICA— SOUTH POLE.

SOUTH POLE.

A total of 380 electron micrographs and electron diffraction patterns of 93 snow crystal nuclei were analyzed in this observation. The nuclei were identified as mainly elay imperals and sodium chloride particles. The clay mineral nuclei were illite 20% kaoline 8%, halloysite 4%, vermiculite 3%, and related minerals 24%. For the other nuclei, sodium chloride accounted for 20%, and unidentified nu lei accounted for 5%. Fifteen percent of the snow crystals did not appear to have nuclei. Therefore, all nuclei found in snow crystals were terrestrial substances from oceans and

continents The shapes of snow crystals were single bullets, combinations of bullets, and hexagonal hollow column. The snow crystals formed at temperatures from -30 to -35C. The snow crystal diameters were from 0.1 to 1.0 mm. The mean mass concentration of sodium chloride in snow crystals was 40 6 ppb and that of clay minerals was 15 4 ppb. The sodium chloride nucleus concentration coincided within the experimental error with data taken from the chemical analysis of the South Pole snow cover made by several workers It was concluded that most of the sodium chloride contained in the South Pole snow cover was due to the sodium chloride nuclei of snow crystals nuclei of snow crystals

OPTICAL PROPERTIES OF SALT ICE.

Lane, J.W., 1975, 15(73), Symposium on Remote Sensing in Glaciology, Cambridge, 16-20 September, 1974, p.363-372, 12 refs., In English with French and German summaries. Includes discussion. 66 refs.

SALT ICE, ICE OPTICS, LIGHT SCATTERING The dependence of the extinction coefficient on salinity was investigated for both NaCl-ice and sali-ice made from the dependence of the estinction coefficient on sainity was investigated for both NaCl-ice and salt-ice made from natural sea-water. Specimens were prepared under a variety of conditions and examined over the wavelength range 4,000 to 8,000 A. The effects of scattering from air bubbles trapped in the ice were examined for ice made from distilled water. It was found that the method of preparing samples markedly affected their structure, but that, when prepared in the same manner, salt-ice made from natural sea-water and NaCl-ice did not show significantly different transmission properties. It was found that, for a wavelength of 6328 A, the data could be fit to the relation ke=[167-085 exp (-0.27x)/cm within an uncertainty of 26%, where ke is the extinction coefficient, and x is the salimity of the ice in g/kg. Within an uncertainty of 10%, there was no variation in transmission for ice at the same temperature and salimity over the wavelength range 4000 to 8000 A. All measurements were made at a temperature of -200C.

MECHANISMS OF CRACK GROWTH IN QUARTZ.

Martin, R.J., III, et al, Dec. 10, 1975, 80(35), p.4837-4844, 21 refs. Durham, W.B.

30-3068

ROCKS, CRACK PROPAGATION, WATER TRANSPORT, QUARTZ.

TRANSPORT, QUARTZ.

A previous study of time-dependent crack growth in single-crystal quartz has been expanded to examine the possibility of microfracturing events during stable crack growth, to look for evidence of plastic deformation associated with crack propagation, and to determine the dependence of crack growth on crystallographic orientation. No discernible effect of orientation on the temperature or change in applied stress or partial in visure of water dependencies during sequential crack g. ... episodes was observed, and no correlation was for ... ectiveen observed microfracturing events and the rate of crack propagation. However, the magnitude of the applied stress to achieve the desired rates of crack extension did vary with orientation. No evidence of plastic deformation has been found in samples of quartz undergoing time-dependent crack growth at temperatures up to 250C. Some Dauphine twins have been observed at temperatures above 125C. The fact that the stress, temperature, and water dependencies are independent or orientation is interpreted to suggest that the observed time-dependent cracking is controlled by the transport of water to the crack tip.

MP 856 GENERAL CONSIDERATIONS FOR DRILL SYSTEM DESIGN.

Mellor, M., et al. Ice core drilling, edited by J.F. actistoesser, Lincoln, University of Nebraska Press, 1976, p.77-111, 58 refs. Selimann, P.V.

30-3483

ICE CORING DRILLS, DRILLING, ROTARY DRILLING, THERMAL DRILLS

DRILLING, THERMAL DRILLS
Drilling systems are discussed in general terms, component functions common to all systems are identified, and a simple classification is drawn up in order to outline relations between penetration, material removal, hole wall support, and ground conditions. Energy and power requirements for penetration of ice and frozen ground are analyzed for both mechanical and thermal processes. An electromechanical coring drill and thermal processes An electromechanical coring drill has been used for deep drilling in Greenland and Antarctica Thermal drills have also been used for boring holes in ice Thermal drills have also been used for borng holes in ice although they are no' as efficient, in energetic terms, as mechanical drills Power requirements for removal of material and for hoisting of drill strings are considered, and total power requirements for complete systems are assessed.

Performance data for drilling systems working in ice and frozen ground are reviewed, and results are analyzed to obtain specific energy values. Specific energy data are assembled for drag-bit cutting, normal impact and identation, liquid jet attack, and thermal penetration. Torque and axial for capabilities of typical rotary drilling systems are reviewed and analyzed. The overall intent is to provide data and quantitive guidance tast can lead to systemside data and quantitive guidance tast can lead to systemside design procedures for drilling systems for cold regions (Auth. mod.)

COMPUTER SIMULATION OF THE SNOW-MELT AND SOIL THERMAL REGIME AT BAR-ROW, ALASKA.

Outcalt, S I., et al, Oct. 1975, 11(5), p.709-715, 17 refs. For another version of this paper see 29-4001. Goodwin, C., Weller, G., Brown, J.

COMPUTERIZED SIMULATION, SNOW TEM-PERATURE, SOIL TEMPERATURE, THERMAL DIFFUSION, SNOW FENCES, WATER SUPPLY. DIFFUSION, SNOW FENCES, WATER SUPPLY. An annual snow-soil simulator for arctic tundra was developed by using coupled models of surface equilibrium temperature and substrate thermal diffusion. Snow ripening, melt, and accumulation are modeled in the simulator which is forced with daily weather data. The simulator predicts that a snow fence array capable of producing drift deeper than 4.2 m will initiate a permanent snowfield at Barrow, Alaska Such a man-induced snowfield could serve as a reliable source of freshwater for Barrow and similar villages in the north slope region of Alaska Further analysis indicated that albedo reduction due to dust fall, snow removal, etc., is dominant over aerodynamic effects in producing the early spring meltout observed at Barrow Village

MP 858 FORCES ON AN ICE BOOM IN THE BEAU-HARNOIS CANAL

HARNOIS CANAL.

Perham, R.E., et al, International Symposium on Ice
Problems, 3rd, Hanover, New Hampshire, 18-21 August 1975. Proceedings, International Association of
Hydraulic Research, 1975, p.397-407, 7 refs. Racicot, L.

30-2743 ICE BOOMS, SHEAR STRESS, ICE PRESSURE. LOADS (FORCES).

LOADS (FORCES).

Ice booms are used to hasten the formation of a stable ice cover in early winter. Their main function is to reduce the area of open water where large amounts of ice floes and frazile ice can be generated This ice, if uncontrolled, can cause an ice jam or blockage at power house intakes and restrict its generating capacity A particular function of the forebay ice boom of the Beauharmois Power House is to prevent any ice upstream from moving down into the forebay. In the winter of 1974-75 CRREL obtained force measurements of both cross stream and downstream components in the forebay ice boom The purpose of this paper is to report these forces and their variations A limited amount of supplemental data such as water flow, ice thickness, and canal dimensions is provided All of the information should help in the understanding of interaction between an ice boom and its ice cover.

30-3095 ICE PRESSURE, HYDRAULIC STRUCTURES, PILE STRUCTURES, MODELS, LABORATORY TECHNIQUES.

TECHNIQUES.

Laboratory tests on freshwater nee were conducted by using model structures of various geometries. Vertical and sloping pile sections with diameters up to 36 in (91.4 cm) were pushed through the nee with an active testing system. The test variables investigated were size, shape, velocity, and slope or angle from the vertical. The data gathered in this study indicates that nominal ice pressure vanes indirectly with pile width/ice thickness (D/T) ratio in the range of 110. There was no apparent change in nominal ice pressure due to the change of the pile shape. Data gathered in the velocity tests suggests an inverse effect upon the ice pressure, especially at speeds greater than 3 in 1s (7 6 cm/s). In the sloping pile tests it was found that the ice pressure decreased with an increase in the sloping pile tests that failed in bending was developed. Values for this linear correlation were found graphically. A comparison of the test results with other investigations is also presented.

ARCTIC LANDSCAPES, TREES (PLANTS), FOR-EST SOILS, SOIL CHEMISTRY. ALPINE VEGE-FATION. ALPINE SOILS

This study characterizes upland forest stands in interior Alaska and compares and contrasts their organic and soil properties. Stand data are presented for tree and sapling species in three aspen/bitch and four black spruce stands. Lutter

layers had greater mass and were more acidic beneath black spruce than beneath aspen/birch. Litter beneath aspen/birch contained higher concentrations of C, N, P, Ca, Mg, Mn, and Zn than did black spruce organic layers. Organic layer K and Fe concentrations were similar beneath the two stand groups. Total organic layer N, P, and Zn mass were similar in the two stand groups, more Ca, Mg, and Mn were present beneath hardwoods, and more K was present beneath black spruce. Extractable soil P decreased rapidly with increasing profile depth beneath aspen/birch stands, but increased with depth to a maximum at or below 15-30 cm beneath hardwoods than beneath coniferous communities. Soils beneath the two stand groups could not be consistently separated by differences in pH, %C, %N, or C/N ratio. Percentage soil carbon at all depths and in all stands was closely correlated with %N (r=0 97) and CEC (r=0.98).

ANALYSIS OF WATER FLOW IN DRY SNOW. Colbeck, S.C., June 1976, 12(3), p.523-527, 12 refs. 31-2958

SNOW PERMEABILITY, WATER RETENTION, WATER FLOW, SNOW THERMAL PROPERTIES, SNOW WATER CONTENT, METAMORPHISM (SNOW), WET SNOW, SNOW HYDROLOGY.

The equations describing water movement in a dry snow cover are derived, and examples of flow through ripe, refrozen, and fresh snows are given. The grain size of snow has a large effect on the timing of water discharge. Water is retained by dry snow to raise its temperature and satisfy the irreducible water saturation. These requirements delay and reduce runoff following rain on dry snow.

ICE CORING DRILLS, DRILLING, FIRN

The USA CRREL shallow drill is an electroniechanical device designed for continuous conng in firm and ice to a depth of 100 m. The drill bores a 14-cm-diameter hole while obtaining a core 10 cm in diameter at a penetration rate up to 1 m/min in -20C ice. The cultings are transported by spiral brush auger flights to a container above the corestorage section. The core and cultings are removed from the drill after each 1 m run. Additional components

include: 100 m of a seven-conductor electromechanical cable, a 6.8-m tower, a hoist which is ski-mounted, and a three-phase 220-V AC gasoline generator. All the equipment has been designed to be transported in a Twin Otter ski-equipped plane and assembled and operated by two men. The total weight of the drill and associated components is 818 kg. The minimum estimated time required to drill 100 m and retrieve core is 15 hours. Excellent is \$18 kg. The minimum estimated time required to drill 100 m and retrieve core is 15 hours. Excellent core was obtained in a record drilling time of 15 hr from a 100-m hole drilled in early Nov at the South Pole under the new geodesic dome. A second 100-m hole was drilled on the Ross Ice Shelf.

ICE CORES, COLD STORAGE.

The U.S. Army Cold Regions Research and Engineering Laboratory (USA CRREL) has responsibility for the central storage and curatorial activities of the ice cores recovered in the Office of Polar Programs/National Science Foundation (OPP/NSF) Arctic and Antarctic research programs — The main purpose of the central ice-core storage facility is to handle, process, catalog and distribute the ice cores drilled in the polar regions to OPP-approved recipients for glaciological research — Under the agreement with OPP, the ice cores are stored at CRREL, and in a commercial freezer facility at Littletown, N H; a technician handles and catalogs them. A core data bank is maintained for retrieval and information exchange, and starting with the Dye 3 ice core, is being computerzed. The storage facilities are described. Recent developments include a cooperative analysis program between CRREL, the University of Copenhagen, and the University of Bern, a particle analysis lab, a core stratigraphy and logging routine, and a surface pit/ice-core correlation and logging routine, and a surface pit/ice-core correlation

MP 875 HOVERCRAFT GROUND CONTACT DIREC-TIONAL CONTROL DEVICES.

Abele, G., International Hovering Craft, Hydrofoil and Advanced Transit Systems Conference, 2nd, Amsterdam, May 17-20, 1976. Proceedings, London, Kalerglic Publications, 1976, p.51-59, 6 refs.

ALL TERRAIN VEHICLES, AIR CUSHION VEHI-CLES, VEHICLE WHEELS, ENVIRONMENTAL IMPACT, TUNDRA TERRAIN, IMPACT.

IMPACI, IDDDRA IERRAIN, IMPACIT.

The maneuverability of a hovercraft can become a serious operational problem where the craft's travel route is restricted by obstacles or requires close-quarter turns, and during travel on slopes and in crosswind conditions. While improvement and perfection of serodynamic methods may be a more desirable approach, there is a practical limit to there methods, and the use of ground contact devices requires consideration to provide more positive directional control. Wheels deserve special attention and therefore are analyzed in more details. and the use of ground contact devices requires consideration to provide more positive directional control. Wheels deserve special attention, and therefore are analyzed in more detail because of their obvious application on a variety of land terrains. Brake rods and harrows are more suitable on water, ice and snow. The saucer would cause the least ecological impact on fragilic organic terrains such as tundra. The use of controlled ground contact with skirt sections having retractable rollers or special wearing surfaces may represent the least significant change to the basic design of the craft or its components. The relative directional stability is evaluated in terms of the total yawing moments produced by a variety of wheel arrangements (single, dual, tandem), location on the craft, and operational modes (free-rolling, braked, or a combination of the two). The available moments are plotted against the yaw angle of the craft to determine the most effective operational mode with a particular which arrangement for any yaw condition. The analysis is limited to retractable devices which act as moment-producing brakes or rollers and do not serve as either propulsion or load support aids. load support aids.

SPREA OF CETYL-1-C14 ALCOHOL ON A

MELTING SNOW SURFACE.

EVAPORATION.

The primary objective of the study was to gain information on the rate of spread of cetyl alcohol on a melting snow surface. Point applications of radioactive cetyl-1-Cl4 alcohol were placed on the surface of snow contained in cubical wooden boxes 25 cm on each side. The boxes with snow were placed in a controlled environment of 2C and with a relative humidity of 25%. Under the study conditions, cetyl alcohol spread as far as 10 cm within 1 hr and 15 min. Patribution of the alcohol over the surface was highly variable. (Auth.)

FLOATING ICE.

ON THE DETERMINATION OF HORIZONTAL FORCES A FLOATING ICE PLATE EXERTS ON A STRUCTURE.

Kerr, A.D., 1978, 20(82), p.123-134, 26 refs.

32-4451 PRESSURE, ICE LOADS, ICE COVER STRENGTH, STRUCTURES, LOADS (FORCES),

FLOATING ICE.

At first, the general approach for calculating the horizontal forces an ice cover exerts on structures is discussed. Ice-force determination consists of two parts: (1) the analysis of the in-plane forces, assuming that the ice cover remains intact; and (2) the use of a failure criterion, because an ice force cannot be larger than the force capable of breaking up the ice cover. For an estimate of the largest ice force an elastic plate analysis and a failure criterion are often sufficient. A review of the literature revealed that in the majority of the analyses, it is assumed that the failure load is directly related to a "crushing strength" of the ice cover. Observations in the field and tests in the laboratory show, however, that in some instances the ice cover failed by buckling. Subsequently, the ice-force analyses based on the buckling failure mechanism are reviewed, and their shortcomings are pointed out. A new method of analysis, which is based on the buckling of a floating ice wedge, is then presented.

SNOW COVER, RUNOFF, MODELS, CANADA— LABRADOR.

A physically based model of the movement of water through snowpacks was used to calculate hydrographs generated by durnal waves of snowmelt on the tundra and in the boreal forest of subarctic Labrador in the model was tested against measured hydrographs from hillside plots that sampled a range of aspect, gradient and length, vegetative cover, and snow depth and density. The model yielded good results, particularly in the prediction of peak runoff sates, though there was a slight overestimate of the lag time. A comparison of predictions with field measurements indicated that given the ranges ever which each of the controls is likely to say, the two most critical factors controlling the hydrograph are the snow depth and the melt rate, which must be predicted precisely for short time intervals. Permeability of the snowpack is another important control, but it can be estimated closely from published values.

AIR CUSHION VEHICLES, SNOW DEPTH, ERO-SION, SURFACE PROPERTIES, TESTS

SION, SURFACE PROPERTIES, TESTS
Travel with an SK-5 ACV over soft snow results in surface deformation/erosion of a few inches, caused primarily by rear skirt drag, on windswept snow only scratches can be seen. During hovering on soft snow, deformation below the cushion chamber usually does not exceed a few inches. The action of the air flow (escape velocity 70 to 120 ft/sec) produces a 1-ft ditch below the peripheral skirt in less than a minute, thereafter the extent of crossion does not increase appreciably during continued hovering. A partial seal between the inner face of the skirt (above fingers) and the snow surface may easit, arresting further settling of the tween the inner face of the skirt (above lingers) and the schicle. Relatively cobesivelayers of snow surface may exist, arresting, further settling of the schicle. Relatively cobesivelayers of snow such as windslabs and crusts are not eroded. A level snow cover, regardless of how deep or soft, does not appear to be capble of immobilizing an ACV of this and larger size. Some operational problems and their degree of severity, such as visibility, snow accumulation and addresson to vehicle skirt drag, effect of terrain surface porosity and presence of vegetation, are also discussed.

THERMAL ANALYSIS, FROZEN GROUND PHYSICS, UNFROZEN WATER CONTENT, CLAY MINERALS, ICE WATER INTERFACE, LOW TEMPERATURE TESTS.

The author discusses the low temperature behavior samples of frozen soils taken from the dry valleys of Antarctica. The samples were composed of various clay minerals and had varying water contents. It is demonstrated that some of the water remains unfrozen and that there is a dependency between the unfrozer portion and the surface area of the sample. It was pointed out that problems arising from the unfrozer water content of soils are of great interest to CRREL researchers as is the analysis of ice cores from Greenland and Antarctica as a technique for establishing past climates and in predicting future climates.

WASTE TREATMENT, WATER TREATMENT, WATER CHEMISTRY, SEEPAGE, SOIL CHEMISTRY, WASTE DISPOSAL

TRY, WASTE DISPOSAL.

The capacity of a slow infiltration land treatment system to removate wastewater in cold regions was investigated using six outdoor test cells. The principal mechanisms for nitrogen removal were found to be plant uptake and dentirification, in the surface soil tayer, heavy metals were removed by softword or precipitation in the top few centimeters of soil. Nitrogen removal was found to be seasonally dependent, the greatest losses occurring in the spring and summer and the least during fall and winter. This was due to the absence of plant uptake during winter and the effect of temperature on the conversion of ammonium to nitrate nitrogen nutrification), which caused significant amounts of NH4 to temperature on the conversion of ammonium to nitrate nitrogen finitification), which caused significant amounts of NH4 to be stored during winter and released in spring, giving rise to a period of high NO3 concentration in the leachate Application of 15 cm week of secendary effluent to study from son resulted in diminished water quality (>10 mg. 1 of nitrate-N) during most of the year. With the exception of this heavy treatment experiment heavy metals and phosphonius were confined to the top 15 cm of the soil. Application of effluents containing ppin levels of heavy metals on all of other water quality parameters (organic-C, BOD), suspended soils, leval coliform) renovation of the wastewater was exentially complete.

Using available atmospheric pressure and ocean current data Using available atmospheric pressure and ocean current data and estimating non-local stress transferral through the ice cover by employing a viscous drift model in the infinite boundary limit, predicted drift rates for one Russian and two US drifting stations are made over the time period May 1962 to April 1964. The viscosity values giving the best fit between observed and predicted values show a pronounced winter increase that correlates well with the ice growth rate. Phiscally this suggests that ice drift rates (for a given wind field) tend to decrease in winter because of increased stress transferral through the ice cover. An empirical linear relationship between viscosity and ice growth rate is derived which yields predictions in reasonable agreement with both long (yearly) and short term (monthly) observed drift rates.

SOIL FREEZING, SOIL STRUCTURE, WATER TABLE, GROUND ICE.

The periodic frozen structure of a glacially-deposited silt The periodic froren structure of a glacially-deposited silt soal is analyzed using a metric grouping of sizes. Four specimens were frozen simultaneously in open-system freezing with initial water tables ranging from 15 cm (6 in). It is not 105 cm (42 in). Rate of freezing varied from near zero to 0.80 mm/hr. Measurements on the average thekness of individual toe layers and residual soil layers are tabulated and graphed for each specimen, with water-table depth and rate-of-freezing as independent variables. The data show that the ice-layer thickness decreases continuously with freezing ing rate for each of the four water-table depths. The maximum ice-layer thickness (45 mm) occurred with the highest water table and the slowest freezing. In contrast, the residual soil layer develops a maximum thickness thickness for this soil in the 0.30 to 0.40 mm/hr range of freezing rates. The peak value (2.5 mm) occurred with water table depths of 45 cm (18 in) and 75 cm (30 in). In addition, the two specimens with the highest water tables developed a more recorders each at very layer than the freeze of freeze for the state of a major secondary peak at very slow rates of freezing (less than 0.10 mm/hr), giving evidence of a separate mode of

REMOTE SENSING. AERIAL SURVEYS, SPACE-BORNE PHOTOGRAPHY, ENVIRONMENTS, UNITED STATES—NEW ENGLAND.

BORNE PHOTOGRAPHT, ENVIRONMENTAL, UNITED STATES—NEW ENGLAND.

The utility of satellite, high altitude and low altitude aerial imagery is presently being critically evaluated by the Corps of Engineers. The most significant contribution to date has been to increase confidence limits by more accurately estimating parameters used in models. Within the last three years several new cooperative remote sensing programs addressing environmental and hydrologic problems have been implemented. The objectives of these programs were to determine the availability, type, scale and resolution required and to show how remote sensing methods can be utilized to augment or update conventional procedures. Imagery from LANDSAT mission provided valuable information for site evaluation, definition of geologic lineations and monitoring snow and ice accumulation and ablation. The Skylab program has defined the detail of land use mapping that can be accomplished from the \$190A and \$190B photography. Low altitude aircraft photography (scale 133,600) was used to determine the location of materials at a potential dam construction site which could allow a large cost saving for transportation of material as compared to original design estimates. In another program, the effect of inundation at six New Engl-ind flood control reservoirs was investigated. The extent and severity of tree damage were mapped and analyzed statistically. These results will be used by the The extent and severity of tree damage were mapped and analyzed statistically These results will be used by the Corps in the reservoir management program

MP 914 EVALUATION AND RECOMMENDATIONS FOR SNOWDRIFT CONTROL AT FAA ILS FACILITIES, BARROW AND DEADHORSE, ALASKA, FINAL REPORT.

Calkins, D.J., Sep. 1976, FAA-NA-76-165, 41p., ADA-030 401.

SNOWDRIFTS, SNOW FENCES, UNITED STATES—ALASKA—BARROW, UNITED STATES—ALASKA—DEADHORSE.

STATES- ALASKA—DEADHORSE.

The easting snowdrifting conditions are described at the Barrow and Deadhorse airfields and recommendations made for minimizing the drifting snow at the ILS facilities. The problem of drifting snow at the localiter and glide slope facilities was a result of the structures themselves creating drifts and causing outages. The most economical method of eliminating the problem at the glide slope was relocation of the instrument shelters such that they are not in line with the antenna masts and the prevailing wind direction. The localizer snowdrifts were caused by the bulkiness of the supporting structure carrying the antenna, although it is elevated on piles severe turbulence develops behind the structure and the snow deposits. Wooden snowlences, 10 ft high, in parallel rows 200 ft apart vill control the snow during an average snow year. Meles studies of each alternative method were carried out to validate the various proposals. (Auth.)

APOR PRESSURE OF 2,4,6-TRINITROTOL-UENE BY A GAS CHROMATOGRAPHIC HEADSPACE TECHNIQUE.

eggett, D.C. 1977, Vol.133, p.83-90, 23 refs.

VAPOR PRESSURE, GAS CHROMATOGRAPHY, TRINITROTOLUENE.

TRINITROTOLUENE.

The vapor pressure of 2,4,6-trinitrotoluene was determined by a gas chromatographic headspace technique. The vapor pressure from 12-40C was derived from the experimental data using the ideal gas law and then compared to extrapolations of literature data obtained by the Knudsen effusion technique. Excellent agreement was obtained. Advantages of the chromatographic headspace method over the effusion method were: (1) scrupulous purity was found to be unnecessary since volatile impurities were chromatographically separated fr in the compound of interest, (2) the method was highly sensitive using an electron capture detector, and (3) the method was experimentally simple, requiring materials that are readily available, 1 e., a gas chromatograph, a temperature bath, a few septum-capped bottles, and gas-tight syringes.

RESEARCH PROJECTS, WATERSHEDS, ENVI-RONMENTS, INTERNATIONAL COOPERA-TION

RONMENTS, INTERNATIONAL COOPERATION.

Much environmental research (both small scale and large)
may logically be conducted within the larger context of
entire drainage basins—Research Watersheds. These are
catchments which represent major environmental settings (e.g.,
Arctic tundra, substrict taiga) and are specifically dedicated
to research. The hydrologic cycle of a complete catchment
considered from precipitation through basin yield provides
a functional and conceptual base for considering mass, nutrent,
and energy transfer questions relevant to ecosystem functioning. With proper planning and execution, advantages to
be gained may include economy of effort, better cooperation
between disciplines, improved application of results to realworld problems, and enhanced potential for comparative studies among circumpolar settings. In high latitudes, where
climate, transportation and logistics, available scientific manpower, and lack of good background data often combine
to render research both difficult and expensive, increased
efficiency through integration of complementary biological
and physical studies is especially attractive. In 197475 a start was made toward such a circumpolar program
Through the International Hydrological Decade (HHD), initial
meetings of Swedish, Canadian, and US scientists have
considered objectives of facilitating communication and data
exchange, and ultimately improving understanding of hydrologic functioning in high-latitude environments. In Alaska
the 104-sq-km Canbou-Poker Creeks Research Watershed
provides one example of multi-disciplinary, multi-agency research into environmental and hydrological behaviour of
subarctic uplands, with provision for physical and biological
investigations and experimentation. Similar circumpolar
efforts should prove useful in a wide variety of disciplinespecific and integrated scientific efforts.

WASTE TREATMENT, WATER TREATMENT. GATION, UNITED STATES—WASHINGTON— QUINCY, UNITED STATES—CALIFORNIA—

MANTECA.

Evaluations of long-term systems for wastewater disposal on land by slow infiltration at Manteca, California, and Quincy, Washington, are presented Factors considered include site history, operational characteristics. Domestic undisinfected wastewater has been applied at these locations by flood irrigation for up to 20 years. At Manteca, forage vegetation (rye grass) has been continuously maintained while at Quincy a crop rotation has been practiced at Quincy has been relatively heavily loaded by application of approximately 15 cm/A (6 in./A) per week while at Manteca an average of only 4 5 cm/A (1.8 in./A) of wastewater has been applied per week. At both sites a control field and two disposal fields were investigated for companson Representative soil samples were collected at intervals to a depth of 150 cm. These were analyzed for about 30 pertinent chemical parameters including total and plant-available heavy metals.

Soil solution samples were collected. pertinent chemical parameters including total and plant-available heavy metals Soil solution samples were collected at 80- and 160-cm depths with suction lysameters. Pretreatment water samples, peripheral drainage water and ground water samples were also collected. All water samples were analyzed in the fields for pH, NH4-N, NO3-N and ortho-P during three periods in 1974.

PROPOSED SIZE CLASSIFICATION FOR THE TEXTURE OF FROZEN EARTH MATERIALS. McGaw, R., 1975, 10p., Presented at Les problèmes posés par la gélifraction. Recherches fondamentales et appliquées. Colloque interdisciplanaire, Paris-Le Havre, 23-25 April, 1975. Report No.311. 4 refs. 32-626

FROZEN GROUND, SOIL STRUCTURE, CLASSIFICATIONS, GROUND ICE.

SIFICATIONS, GROUND ICE.
The macroscopic fabric, or texture, of frozen earth materials represents a point-by-point summation of the microscopic nucleation, moisture flow, and heat flow around and between individual mineral particles. As such, frozen texture is intimately related to the basic mechanisms of ice segregation. A study of the details of frozen texture can lead to fundamental new knowledge on the formation and structural effects of segregated ice. A size classification derived from laboratory tests is proposed for the systematic measurement of the characteristic (banded) element of interleaved soil and ice in fine-grained granular materials. Graphs are presented showing the relationship between the frozen texture of New Hampshire. Sitt and measured values of freezing rate as determined by the 0°C isotherm.

INTERESTING FEATURES OF RADAR IMAGE-RY OF ICE-COVERED NORTH SLOPE LAKES. Weeks, W.F., et al, 1977, 18(78), p.129-136, In English with French and German summaries. 15 refs Sellmann, P.V., Campbell, W.J.

LAKE ICE, RADAR PHOTOGRAPHY, ICE WATER INTERFACE, ICE SOLID INTERFACE, ICE SOLID INTERFACE, ICE COVER THICKNESS, REFLECTIVITY, UNITED STATES—ALASKA—NORTH SLOPE Side-looking airborne radar (SLAR) imagery obtained in April-May 1974 from the North Slope of Alaska between Barrow and Harrison Bay indicates that funda lakes can be separated into two classes based on the strength of the radar returns Correlations between the areal patients of the returns, limits ground observations on lake depths and water compositions, and information obtained from LANDSAT imagery strongly suggest that areas of fresh water lakes giving weak returns are frozen completely to the bottom while areas giving strong returns are not. This is a reasonable interpretation inasmuch as the reflection coefficient associated with the high-dielectire-LAKE ICE. RADAR PHOTOGRAPHY. as the reflection coefficient associated with the high-dielectricas the relication coefficient associated with the high-dielectric-contrast to-e-water interface would be roughly twelve times that associated with the low-contrast icc-soil interface. Brackish lakes also give weak returns even when they are not completely frozen. This is the result of the brine present in the lower portion of the ice cover limiting the

penetration of the X-band radiation into the ice. The ability to separate tundra lakes rapidly and easily into these two classes via SLAR should be useful in understanding a wide variety of problems.

SNOW COVER EFFECT, MILITARY OPERA-TION, MILITARY EQUIPMENT.

TION, MILITARY EQUIPMENT.

Pertinent properties of a snow cover are thicknesses of individual layers, snow density, hardness, grain sizes and temperatures. A snow cover is subject to constant metamorphism and its occurrence is subject to seasonal and geographic distribution. A snow cover is a serious obstacle for traffic, especially military transportation. As a maternal, snow may be used for shelters, camouflage and fortification. Observations of attenuation of fast projectiles and fragments are reported. It is concluded that snow may be a maternal seriously affecting fuze mechanisms of certain projectiles and may degrade ammunition effects. Cited and recommended literature covers most of the aspects of the role of snow in warfare.

CHETTES, PPELINES, POWER LINE ICING, FROST PROTECTION.

This report represents information on utility distribution systems gathered on a study trip to Scandinavia and Great British and Iceland. The information concerns new technology and materials in cold weather related problems and solutions. The distribution systems involved are water and sewage lines, vacuum sewage and pneumatic solid waste collection lines, heat distribution lines and electrical transmission lines. In Sweden much information was obtained on plastic pipes for water and sewage lines, and frost penetration protection. There are large district heating systems in operation and much information was found on heat distribution pipe systems and long distance heat transmission. In Norway, where almost all electricity is produced by hydroelectic, stations, information was collected on electric transmission line iscing problems and self supporting aerial cables for electrical distribution. A wealth of information was arbitred in London where the water and sewage systems are among the oldest and largest in the world and where some material and methods have a long history of success and other new ones are being introduced. District heating technology is also highly developed in London, but large systems have not yet evolved. Pneumatic solid wastes collection systems are being introduced. systems have not yet evolved. Pricum collection systems are being introduced

SNOW VEHICLES

Trafficability of terrain is a function of soft soil, hard in rough ground, geometric obstacles, segetation, and the riserine environment. All of these terrain aspects are altered by cold temperatures and snow cover. This paper examines the effect of snow cover on obstacle crossing performance of vehicles. The mathematical expressions describing step negotiation, trends crossing. In slope climbing on snow covered obstacles are given in terms of tracked vehicles on snow covered slopes, stream crossings, steps and trenches were conducted, and some of the results were compared with computed values. Differences between computed and experimental values are attributed to negrecting slip-sinkage and track deflection in the computations. (Auth.)

Air photos of a stiall ice jam on the Pemigewasett River near Plymouth, N.H., were taken three days after the jam and compared with photos taken after the ice went out. The winter photos show a marked and sudden decrease the winter photos show a marked and sudden decrease in flow size apparently indicative of faster and longer movement of the ice. The spring photos show a number of shallows and obstructions that apparently had no effect on the ice movement. It is concluded that this jam was caused by a change in slope and subsequent reduction in velocity.

NUMERICAL SIMULATION OF AIR BUBBLER SYSTEMS

Ashton, G.D., National Hydrotechnical Conference, Ashton, G.D., National rygnotectimes Constitute, 3rd (with the participation of the Municipal Section), Quebec, May 30-31, 1977. Proceedings, Université Laval, Canadian Society for Civil Engineering, 1977, p. 765-778. In English with French summary. 7 refs. p.765-778, In English with French summary.

BUBBLING, ICE PREVENTION, ICE CONTROL, HEAT TRANSFER, MECHANICAL ICE PRE-VENTION, EQUIPMENT, ANALYSIS (MATH-EMATICS).

The use of air bubbler systems to suppress ice formation is a technique which has been applied in a variety of situations and with saying degrees of success. Recently two-dimensional line source bubbler systems were analyzed (Ashton. 1974) in an effort to make available a tool which may be used in the design of a bubbler installation. That analysis was a steady-state evaluation of the melting rate of an ice cover above a bubbler system predicted on the basis of the input variables (depth, air discharge rate, water temperature). In actual operation, however, a bubbler "sees" changing conditions such as diurnal and longer-term weather conditions, varying water temperatures, and depletion of the available thermal reserve. The simulation presented herm uses the steady-state analysis developed earlier (Ashton, 1974) and steps it in time with each new condition determined from the results of the previous time step. In this sense the analysis herein may be considered quasi-steady. Results of the simulation are presented for an example case for a winter in Duluth. Minnesota and illustrate selection of time step size, effect of various strategies of intermittent operation, and variation in width of open water area with changing weather conditions. The use of air bubbler systems to suppress ice formation

Results obtained with a unique dual-antenna impulse radar system used to profile first- and multi-year sea ice near Prudhoe Bay, Alaska, are discussed. A description of the radar system is given along with representative field data. From the radar impulse travel times obtained with the use of dual antennas, calculations of thickness, electromagnetic impulse velocity and effective dielectric constant of the ice were made. Ice thicknesses determined by direct measurement and those calculated using the radar impulse travel times were found to be in good agreement. Continuous ice thickness profiles obtained with the radar were analyzed to provide representative cross sections reveal the undulating bottom surface relief of both ice types. Calculations are presented that indicate a significant amount of oil could be trapped within this bottom relief should the oil be released under the ice from a sea-floor oil-production system.

Soils of continental Antarctica are forming in one of the most severe terrestrial environments. Continuously low temperatures and the searcity of water in the liquid state result in the development of desert-type soils. In an earlier experiment to determine the degree to which radioactive NaCl36 would migrate from a shallow point source in permitrost, movement was observed. To confirm this result, a similar experiment involving Na22Cl has been conducted. Significantly less movement of the Na22 iou was observed. Ionic movement in the unifozen interfacial films at mineral surfaces in frozen ground is held to be important in chemical weathering in Antarctic and other desert soils. weathering in Antarctic and other desert soils

UNITED STATES—ALASKA—BARROW.

The Barrow environment can be characterized as follows.

(1) Situated at the northern extremity of the Arctic Coastal Plain, it has a climste consisting of long, dry, cold winters and short, moist, cool summers. The latter is moderated by the influence of the Arctic Ocean. (2) Vegetation is meadow-like with an abundance of sedges, grasses, herbs and a few dwarf shrub species. (3) Sulls are predominantly wet, with an average seasonal thaw of apposimately 40 cm. (4) Perennially frozen ground underlies the antire land surface to depths in access of 300 meters. (5) The near-surface coastal plann sediments are manne in origin and mid-to late-Pleistocene in age. (6) The tundra landscape is charcterized by active geomorphic processes such as lake erosion, polygonal ground formation and frost stirring of the soil.

EFFECTS OF RADIATION PENETRATION ON SNOWMELT RUNOFF HYDROGRAPHS.

Colbeck, S.C., Feb. 1976, 33rd, p.73-82, 10 refs. For this paper in another form see 31-4171.

SNOWMELT, RUNOFF, SOLAR PADIATION, WATER FLOW.

Water flow through the unsaturated portion of a snowpack Water flow through the unsaturated portion of a snowpack to relevalized itsing various assumptions about adiastors penetration into the snow. The results show that for the purposes of hydrologi, forecasting, it is sufficiently accurate to assume that all of the radiation absorption occurs on the surface. The error in the calculation of flow is largest for very shallow snowpacks but this error is reduced by radiation absorption at the base of the snow and by the routing of meltwater through the saturated hasal layer.

ATMOSPHERIC TRACE METALS AND SUL-FATE IN THE GREENLAND ICE SHEET. Herron, M.M., et al, July 1977, 41(7), p.915-920, 22

Langway, C.C., Jr., Weiss, HV., Cragin, J.H. 31-4306

ICE SHEETS, CHEMICAL ANALYSIS, METALS, GREENLAND.

GREENLAND.

Chemical analyses of surface snow and dated deep see core samples from Central Greenland suggest that In. Pb and sulfate are presently being deposited there at two to three times the natural rates. No recent increases in Cd or veneratizations were observed. Pre 1900 see thoses no measurable effect of the activities of man and represents a good natural aerosol baseline. High enrichment factors relative tin average crustal material were observed for In. Po. Cd and sulfate in all samples indicating a natural source other than continental dust is responsible. A high temperature process or vapor phase origin for these enriched elements, possibly volcanism, seems likely.

FREEZE DAMAGE PROTECTION FOR UTILI-TY LINES.

McFadden, T., International Symposium on Cold Regions Engineering, 2nd, Fairbanks, Aug. 12-14, 1976, Proceedings, Fairbanks, University of Alaska, Cold Regions Engineers Professional Association, 1977, p.12-16, 2 refs. 32-284

WATER PIPES, PIPELINE FREEZING, PIPE-LINE INSULATION, ICE PRESSURE.

LINE INSULATION, ICE PRESSURE.

A method for positioning freeze damage and resultant pipe failures was developed using insulation to position the pressure buildup and subsequent damage area. A pressure relief device fabricated largely from common pipe corriponents was designed and tested. Results show that a significant portion of the failures can be eliminated. Experiments into the mechanism involved in pipe freezing has shown that some of the old concepts are incorrect and new insight into the actual freezing process has resulted.

USE OF A LIGHT-COLORED SURFACE TO REDUCE SEASONAL THAW PENETRATION BENEATH EMBANKMENTS ON PERMA-

Berg. R.L., et al, International Symposium on Cold Regions Engineering, 2nd, Fairbanks, Aug. 12-14, 1976, Proceedings, Fairbanks, University of Alaska, Cold Regions Engineers Professional Association, 1977, p.86-99, 9 refs. Quinn, W.F. 32-289

PERMAFROST CONTROL, EMBANKMENTS. THAW DEPTH, SURFACE STRUCTURE, SOLAR RADIATION, ABSORPTIVITY

RADIATION. ABSORPHY11 I
The construction of embankments on permafrost, particularly
in regions where the mean ground temperature is close
to the inclining point, usually results in melting of the permafrost
which may cause excessive settlement. The depth of melting
(than penetration) is considerably increased should the surface (this penetration) is considerably increased should the surface of the embankment be consered with a bitumosous pasement. This increased melting results from greater absorption of solar radiation by the dark surface. A light-colored surface (white traffic paints has been used on the asphalt remay at Thule AB, Greenland (a cold permafront sites and on high-ay test sections rear Fairbanks, Alaika (a warm permafront site). The selection of light-colored uniforming material for embankments on permafront can have a considerable beingin influence on the depth of thaw penetration and ultimate is than consolidation.

PERMAFROST EXCAVATING ATTACHMENT FOR HEAVY BULLDOZERS.

Garfield, D.E., et al. International Symposium on Cold Regions Engineering, 2nd, Fairbanks, Aug. 12-14, 1976, Proceedings, Fairbanks, University of Alaska, Cold. Regions. Engineers. Professional. Association, 1977, p 144-151, 5 refs

Mellor, M

EXCAVATION, FROZEN GRAVEL, FROZEN GROUND STRENGTH

In anticipation of military needs for grading and excavating froren ground an attachment for heavy engineer tractors was developed. The attachment consists of a hydraulically driven bestrontal cutter driam that attaches to build-over push arms, together with an auxiliary power source that attaches to the rear of the tractor. The machine is indicated to break up frozen soil so that it can be liancied by conventional to break upfrozen sod so that it can be landled by conventional carthmoung equipment. Tests in frozen gravel and in rock outcrops demonstrated that the machine and its ceiting pasks could withstand the most severe ceiting conditions that would normally be met. In frozen gravel, ceiting rates at a drum operating depth of 10 ft (0.3 m) averaged 15 ft mm (7.6 mm/s) at a 30-resumm drum speed and 17 ft frimm (8.6 mm/s) at 15 resumm. Operating at the same depth in frozen silt, cutting rates averaged 18 ft min (9.1 mm/s) at both 30-resumm and 15-resumm medium speed, however, cutting rates varied considerably at the lower drum speed. Modifications suggested for future designs include changes in the teeth lacing pattern and changes in the method of attaching the drum to the tractor.

ICE BOOMS, ICE CONTROL, RIVER ICE, LOADS (FORCES), COST ANALYSIS, ECONOM-

ICADS (FORCES), COST ANALYSIS, ECONOM-ICS.

In early winter, ice booms are used to assist nature in quickly forming a solid ice cover on rivers. The open water, insulated in this way, is no longer the source of frazil ice which, in the past, has caused ice jams, flooding, and the loss of electrical generating capacity. They function in other ways as well such as strengthening the ice sheet edge against subsequent damage and restraining its movement. Ice booms are basically lines of floating timbers or pontoons held in place by heavy cable structures connected to buried anchors. They were developed and are used mainly by hydroelectine power groups but they also help facilitate ship navigation in winter. The cost of these ice control devices over the past 17 years has ranged from about \$48/t (\$156/m)\$ to \$333/ft (\$1094/m) with one set costing approximately \$1,500,000. The value of many ice booms can best be related to the cost of replacing the electric power that could be lost if they were not present, as opposed to trying to choose a cost basis for a flood. A rough estimate of \$0.01/kWh for the value of replacement power is used here. The most valuable ice boom could be the Lake Ene Ice boom which saves an estimated \$13,000,000 per year. Next are the ice booms on the Beauharnois Canal which are used with particular operating techniques to save approximately \$4,300,000 per year. Ice booms can also help save millions in shipping costs as well by stopping excessive ice movements during the navigation season in winter on the Great Lakes

RIVER ICE, ICE BREAKUP, ICE LOADS, OFF-SHORE STRUCTURES.

A recently completed bridge across the Yukon River, north of Fairbanks, Alaska, provides an opportunity for studying breakup processes and measuring ice forces on a structure in a major river where ice conditions are near the continental extreme Above the bridge the river flows through the 200-mile long Yukon Flats, a marshy, lake-dotted area. The multiple channels of the river meander back and forth providing a very larse water surface for winter toe production. The multiple channels of the river meander back and forth providing a very large water surface for winter ice production. The winters are long and severely cold with only light snowfall so the Flats produce very large quantities of thick ice which pass through the bridge each spring. The bridge is a six-span continuous orthotropic-deck structure spanning a 2,000-foot channel Five reinforced concrete piers secured to bedrock with prestressed rock anchors are subject to river ice. Steel legs rise from the tops of the piers to carry the deck USACRREL, University of Alaska, and Alaska Department of Highways personnel observed including speed Super 8 movie and 35mm still photographs were taken. Several types of ice failure were observed including crushing along the full width of the piers, splitting, combined splitting and crushing and non-failure

TUNDRA BIOME, SPECTROMETERS.

Infrared gas analytical techniques have made it possible to detect small amounts and changes in carbon dioxide in the environment. The reliability and intercomparison of these measurements depends on the ability to calibrate the IRGA with a high degree of precision and accuracy. A mutual comparison scheme is presented to provide a method for calibrating an infrared gas analyzer and to document changes that occur in CO2 reference gas standards. It is suggested that a need exists to establish a central reference gas laboratory for the purpose of supply investigators with accurate reference gas standards. (Auth.)

WASTEWATER TREATMENT IN COLD RE-GIONS.

Sletten, R.S., et al, 1976, 15p., ADA-026 156, Unpublished report.

Uiga, A. 32-1274

WASTE TREATMENT, WATER TREATMENT, MILITARY FACILITIES.

Wastewater treatment at remote military installations in Alaska Wastewater treatment at remote military installations in Alaska presently consists of aerated lagoons and extended aeration package plants. Although performance data for these systems are either very limited or in most cases nonexistent, indications are that most of these systems can not meet secondary ffluent or 'eria as defined by the EPA. Processes for upgrading to meet the new criteria must be as simple as possible to design, build and operate. In particular, the requirements for operation and maintenance should be minimal due to the remote, isolated nature of most of the camps. Processes which appear to be feasible include land application, intermittent filtration, and variations of ponding.

Data have been presented on the growth and chemical composition of forages when influenced by various application rates of wastewater during 1974 and 1975. The results show that the greatest average annual forage yields and N and Premoval occurred at the highest application rate (15 cm/wk). However, forage removal efficiency of applied N and P was greatest at the lowest application rate of 5 cm/wk. At this rate an average of 97 percent of the applied N and 35 percent of the applied P was contained in the forage Analyses performed in 1974 and 1975 showed a reduction in the levels of K in the soil and forage in 1975, relative to 1974, which indicates a requirement for K fertilization for sustained productivity The reduction in K was related to the large quantities of this element required by crops and its low concentration in the wastewater. Soil analyses also showed reductions in soil pH and total exchangeable cations to levels which could be corrected by liming

32-1528 WASTE DISPOSAL, SOIL CHEMISTRY, MICRO-ELEMENT CONTENT, PLANTS (BOTANY), LAND DEVELOPMENT, SOIL POLLUTION, GRASSES, METALS.

Heavy metal accumulation in soils and forages of a slow infiliration prototype land treatment system over a two year period is discussed. Uptake of heavy metals by plants and soils vaned according to the amounts applied, soil type, and mode of wastewater application. Charlton silt loam soil retained more heavy metals than Windsor sandy loam Heavy metals were confined to the top 15 cm of the soil and vertical movement occurred only in the soil from the treatment receiving the highest application rate (15 cm/wk) Movement of heavy metals in this treatment was thought to be due to a redistribution of organic matter (hydraulic effect), a decrease in soil pH or both. Forages (quack grass) from all the treatments contained much higher concentrations of heavy metals than the control There were significant differences in plant tissue heavy metals accumulation between the different cuts. This was related to the concentration of heavy metals in the applied effluent. Forages from the second cut contained Cd and Ni and to some extent Cu at "toxic" levels, while Zn, Cr, Hg and Pb were present in normal or slightly higher amounts. Spray irrigation of heavy metal-spiked wastewater resulted in much higher concentrations in the plant tissue than in those from flood irrigation treatments. This could be due to absorption of heavy metals by the leaves in the sprayed forages Heavy metal accumulation in soils and forages of a slow of heavy metals by the leaves in the sprayed forages

FREEZE-THAW ENHANCEMENT OF THE DRAINAGE AND CONSOLIDATION OF FINE GRAINED DREDGED MATERIAL IN CON-FINED DISPOSAL AREAS.

A large amount of interest has recently been expressed pertaining to the quantity of physically adsorbed water by the Martian regolith. Thermodynamic calculations based on experimentally determined adsorption and desorption isotherms and extrapolated to subzero temperatures indicate that physical adsorption of more than one or two monomolecular layers is highly unlikely under Martian conditions. Any additional water would find ice to be the state of lowest energy and therefore the most stable form. To test the validity of the thermodynamic calculations, we have measured adsorption and desorption isotherms of sodium monimorillomite at -5C. To a first approximation it was found to be valid A large amount of interest has recently been expressed

ROOF LOADS RESULTING FROM RAIN ON SNOW; RESULTS OF A PHYSICAL MODEL. Colbeck, S.C., Dec. 1977, 4(4), p.482-490, In English with French summary. 11 refs. See also 32-1151 (CR 77-12).

32-1648 ROOFS, SNOW LOADS, RAIN, MATHEMATI-CAL MODELS.

CAL MODELS.

A physical model is used to calculate roof loads due to rain on a snow covered roof. A snow depth of 0.5 m and the twenty-five year rainstorm in Hanover. New Hampshire, are used in the examples. For a flat roof with 10 m parallel flow to gutters, the total liquid weight can increase the roof load by about 50%. The weight of the transient liquid is greatly increased if the mode of flow is radial to central drains and is decreased if the roof is slightly inclined or if significant melt channels form in the basal layer. However, the acting of the snow over its entire depth will still cause a significant weight of transient liquid. Snow drifting can cause very large, local loads but the effects of snow temperature and antecedent mosture are not too important. Depending on the circumstances, the largest load can occur for either a long duration, low intensity rainstorm or a short durition, high intensity rainstorm the former occurs if the saturated layer makes a significant contribution to the total live load whereas the latter occurs when the liquid weight is due mainly to the unsaturated layer. Further study is needed to establish the joint probabilities of combined snow and rain loads, especially when rain and snowmeth occur simultaneously. layer. Further study is needed to establish the joint probabili-ties of combined snow and rain loads, especially when rain and snowmelt occur simultaneously

SEA ICE, WIND FACTORS, VISCOUS FLOW, MATHEMATICAL MODELS, BOUNDARY VALUE PROBLEMS.

VALUE PROBLEMS.

A detailed re-examination of the viscous approach is made by companing predicted with observed ice drift in the Arctic basin over a two-year period employing a viscous constitutive law having both bulk and shear viscosities. Numerical drift calculations for the Arctic Basin are carried out at 4-day intervals over a two-year period employing periodic boundary conditions. Drift predictions are compared with the observed drift of three contemporaneous drifting stations with reasonable agreement. The largest errors are found to occur in late summer, and may be due to nonsteady current effects. Boundary value calculations show that reduction of the shear viscosity (while still maintaining allarge bulk viscosity) reduces the excessive stiffening often found in viscous models while still maintaining substantial changes in drift direction due to boundaries. Sensitivity studies show steady current effects to be small for drift rates over tens of days but not negligible for cumulative drift over years.

BORNE PHOTOGRAPHY, BATHYMETRY.

Large areas of grounded sea ice have been reported by early arctic explorers and more recently by the U.S. Coast Guard The ESSA, ERTS, NOAA, and DMSP satellites now provide multi-spectral imagery with sufficiently high resolution to allow detailed sequential observations to be made of the movement and spatial extent of arctic sea ice. This report discusses the location, formation, and decay of five large (>30 sq km) islands of grounded sea ice in the southern Chukchi Sea as observed for an extended period of time using satellite imagery. Measurements of the bathymetry around one grounded sea ice feature are presented along with observations made and photos taken from the ice surface. The potential use of these sea ice islands as research stations is also discussed.

GLACIER FLOW, CREVASSES, ICE DEFORMA-TION, STRAIN MEASUREMENT.

TION, STRAIN MEASUREMENT.

Surface deformations in the neighborhood of a crevasse field were measured over short (3 m) gape lengths in order to study flow conditions associated with crevasse formation. The results obtained were unusual in that they were inconsistent with large-scale results found by previous workers it was concluded that the presence of small-scale surface effects, such as fractures, porholes and healed crevasses give rise to small-scale deformation fields with large spatial and temporal variations, and that there is a lower limit of seve length

to similar-scale deformation fields with large spatial and temporal variations and that there is a lower limit of gage length below which deformation measurements pertinent to regional flow phenomena cannot be made. This lower limit is apparently an order of magnitude greater than the spacing of the features which give rise to localized effects.

REMOTE SENSING, MAPPING, PERMAFROST DISTRIBUTION, VEGETATION PATTERNS, SEDIMENT TRANSPORT.

SEDIMENT TRANSPORT.

Physiognomic landscape features were used as geologic and vegetative indicators in preparation of a surficial geology, vegetation, and permafrost map at a scale of 1:1 million using ERTS-1 band 7 imagery. The detail from this map compared favorably with USGS maps at 1 250,000 scale Physical boundaines mapped from ERTS-1 imagery in combination with ground truth obtained from existing small scale maps and other sources resulted in improved and more detailed maps of permafrost terrain and vegetation for the same area. ERTS-1 imagery provides for the first time, a means of monitoring the following regional estuarine processes daily and periodic surface water circulation patterns, changes in the relative sediment load of rivers discharging into the inlet, and, several local patterns not recognized changes in the relative sediment load of rivers discharging into the inlet, and, several local patterns not recognized before, such as a clockwise back eddy offshore from Clam Gulch and a counterclockwise current north of the Forelands. Comparison of ERTS-1 and Manner imagery has revealed that the thermokarst depressions found on the Alaskan North Slope and polygonal patterns on the Yukon River Delta are possibly analogs to some Martian terrain features

SEA ICE, ICE MODELS, ICE MECHANICS, MATHEMATICAL MODELS.

MATHEMATICAL MODELS.
Simulation results for sea ice drift, deformation and ice thickness variations in the Arctic Basin are presented using a dynamic-thermodynamic model which treats the ice as a rigid plastic continuum. Using available observed atmospheric and oceanic forcing data, numerical model simulations are made over a four year long period employing one day time steps in a finite difference code with a resolution of 125km. Drift, deformation, stress and ice thickness time series from the simulation results in the near shore region off the Alaskan and Canadian North slope are reported and briefly examined in light of available observations

DIELECTRIC CONSTANT AND REFLECTION COEFFICIENT OF THE SNOW SURFACE AND NEAR-SURFACE INTERNAL LAYERS IN THE MCMURDO ICE SHELF.

Kovacs, A, et al, Oct 1977, 12(4), p.137-138, 9 refs.

SPOW SURFACE, SNOW ELECTRICAL PROPERTIES, ICE SHELVES, ICE ELECTRICAL PROPERTIES, RADAR ECHOES, ANTARCTICA—MCMURDO ICE SHELF.

—MCMURDO ICE SHELF.

An impulse radar system was used to profile the shape and lateral extent of the brine layer in the McMurdo Ice Shelf.

A small antenna was also used to determine if reflective layers could be detected in the upper 5 m of snow. The radiated impulse center frequency was 626 megahertz with an estimated frequency spectrum of 375 and 875 at the -3 decibel points. The measurement technique is described. The study indicates that layers of dielectric discontinuity can be detected at shallow depths in polar snow. The shallow depth at which the internal layers were detected suggests that they represent density variations in the snow, perhaps associated with summer melt features less than 5 mm thick.

MP 1012 ICEBERG THICKNESS PROFILING USING AN IMPULSE RADAR.

Kovacs, A., Oct. 1977, 12(4), p.140-142, 5 refs.

ICEBERGS, ICE COVER THICKNESS, RADAR ECHOES, MEASURING INSTRUMENTS.

ECHOES, MEASURING INSTRUMENTS.

Thickness measurements taken on a 100 to 500 m tabular iceberg in McMurdo Sound using an impulse radar system are discussed and illustrated

Calculated Jepths of the brine layer at the south and north ends of the iceberg were 13 7 and 17 4 m, respectively

The calculated Interpolation of the ceberg were 13 7 and 17 4 m, respectively

The calculated thickness of the teeberg at station 4.5 and stations 5 through 17 ranged from 900 to 60.5 m

The capparent freeboard-to-thickness ratio was 1 to 5.2, which is higher than the 1 to 3.6 freeboard-to-thickness analysis of Gow (1968, 1-6274) for antarette ice shelves of similar thickness. The data suggest a glacial rather than a shelf origin

TICA—MCMURDO ICE SHELF.

Depth characteristics, lateral continuity, and inland boundary of sea water infiliration in the McMudo Ice Shelf were monitored using a dual-antenna impulse radar profiler. The studies have provided new information on the brine infiliration zone, including data on changes in the elevation of the brine-soaked layer and ice shelf thickness as a function of distance from the shelf edge. The features of the brine layer are described and illustrated. Observations on the glacial ice/saline-ice transition on the Koettlitz Glacier tongue are summarized.

MP 1014 SEA ICE STUDIES IN THE WEDDELL SEA RE-GION ABOARD USCGC BURTON ISLAND. Ackley, S.F., Oct. 1977, 12(4), p 172-173, 2 refs. 32-2123

SEA ICE DISTRIBUTION, ICE COVER THICK-NESS, PACK ICE, ICE SALINITY, WEDDELL SEA.

SEA.

Sea ice studies in the Weddell Sea aboard Burton Island consisted of ice salinity measurements on meltwater from ice cores and thickness measurements taken in drilled holes. Ploes in the northern region were generally thicker than 2 m and in two regions exceeded 3 m on average. At higher latitudes in the middle of the Weddell Sea ice thicknesses exceeded 3 5 m. The thinnest ice was measured at the southernmost locations. It is concluded that advection is an important component in accounting for ice distribution in the Weddell Sea. In vivo fluorescence ineasurements of core meltwater revealed apparent relationships between ice salinity and biological activity (ice algae)

ENGINEERING PROPERTIES OF SNOW.

Mellor, M., 1977, 19(81), p.15-66, In English with French and German summaries. Refs p.62-65.

SNOW IMPURITIES, SNOW MECHANICS, SNOW THERMAL PROPERTIES, SNOW ELECTRICAL PROPERTIES, SNOW OPTICS, ENGINEERING, SNOW CRYSTALS, SNOWFALL, BLOWING SNOW.

NEERING, SNOW CRYSTALS, SNOWFALL, BLOWING SNOW.

The general properties of snow are described with a view to engineering applications of data. Following an introduction and a short note on the origins of snow, data are given for fall velocities of snow particles, and for mass flux and particle concentrations in falling snow and blowing snow. Notes on the structural properties of deposited snow cover grain size, grain bonds, bulk density, overburden pressure, and permeability. A section on impurities deals with stable and radioactive isotopes, chemical impunities, insoluble particles, living organisms, acidity, and gases. Mechanical properties are treated only selectively, and the reader is referred to another paper for comprehensive coverage. The selective treatment deals with stress waves and strain waves, compressibility, effects of volumetric strain on deviatoric strain, and specific energy for comminition on thermal properties covers heat capacity, latent heat, conductivity, diffusivity, heat transfer by vapor diffusion, heat transfer and vapor transport with forced convection, and thermal strain. The section on electrical properties opens with a brief discussion on dielectric properties of ice, and proceeds to a summary of the dielectric properties of ice, and proceeds to a summary of the dielectric properties of see, and proceeds to a summary of the dielectric properties of snow, including dielectric dispersion, permittivity, dielectric loss, and deconductivity. There are also notes on the thermoelectric effect and on electrical charges in falling and blowing snow. The section on optical properties deals with transmission and attenuation of sisble radiation, with spectral reflectance, and will congruence missivity. The review concludes with some comments on engineering problems that involve snow, and the requirements for research and development. (Auth.)

ICEBERGS, ICE ISLANDS, EXPLOSION EF-FECTS.

Past attempts at explosive demolition of icebergs and ice Past attempts at explosive demolition of icebergs and ice islands are reviewed, and more recent studies are described. Relevant properties of ice are compared with those of typical rocks, and data are given for crater blasting in ice and in rocks. Ice island destruction is analyzed for schemes involving (1) crater blasting, (2) blasting in water underneath the ice, (3) bench blasting, and (4) controlled presplit blasting. The analyses favor crater blasting as the most practical method of attack for small bergs and ice islands.

ICEBERG THICKNESS PROFILING.

Kovacs, A., International Conference on Port and Ocean Engineering Under Arctic Conditions, 4th, St. John's, Sept. 26-30, 1977, Vol.2, Memorial University of Newfoundland, 1978, p.766-774, 16 refs.

ICEBERGS, ICE COVER THICKNESS, RADAR ECHOES, PROFILES.

ECHOES, PROFILES.
Results obtained with an impulse radar system used to profile the thickness of a tabular iceberg in McMurdo Sound, Antarctica, and an ice island in the Beaufort Sea near Flaxman Island, Alaska, are presented. Graphic records are shown of the radar impulse travel time which clearly reveal, for the first time, the bottom relief of each ice formation. Also detected and shown are echo signatures from internal cracks and an infiltration-brine layer. The time of flight of the radar impulse in the ice island is compared with a 24 05-m drill hole measurement of the ice thickness. The effective velocity of the radar impulse in the ice island was found to be 0 16 m/ns and the effective delectric constant of the ice to be 3.5. (Auth.) MP 1020

TOWING ICEBERGS.

CLASSIFICATION AND VARIATION OF SEA ICE RIDGING IN THE ARCTIC BASIN Hibler, W.D., III, et al, Jan. 1974, No.23, p.127-146, 16 refs.

Mock, S.J., Tucker, W.B.

28-4069

SEA ICE, ICE STRUCTURE, ICE PRESSURE, ICE MODELS, PRESSURE RIDGES.

MODELS, PRESSURE RIDGES.

A one-parameter model for pressure ridges is developed and compared with good agreement to more than 3000 km of laser profile data taken from November 1970 to February 1973 in the Arctic basin.

Using a parameter called ridging intensity, which may be determined for a region from the mean number of ridges per unit length and the mean ridge height, the number of ridges per kilometer at any height level may be predicted. Results from a study of regional and temporai variation in ridging indicate that although magnitudes of ridging intensity vary in time, the relative regional variations are similar. Consequently, three distinct regions of ridging intensity having relatively stable boundaries can be defined. Annual variation in new ice production due to ridging is sufficiently large to suggest that ridging plays an important role in the overall mass balance of the Arctic basin.

29-72

SEA ICE, CHEMICAL ANALYSIS, SALINITY, ICE COVER THICKNESS.

The salinity distribution in multi-year sea ice is dependent on the ice topography and cannot be adequately represented by a single average profile. The cores collected from by a single average profile. The cores collected from areas beneath surface hummocks generally showed a systematic increase in salinity with depth from 0 per mile at the surface to about 4 per mille at the base. The cores collected from areas beneath surface depressions were much more saline and displayed large salinity fluctuations Salinity observations from sea see of varying thicknesses and ages collected at various Arctic and sub-Antarctic locations revealed collected at various Arctic and sub-Antarctic locations revealed a strong correlation between the average salinity of the ice Sand the ice thickness h. For salinity scriples collected from cold sea ice at the end of the growth season, this relationship can be represented by two linear equations: S=14.24-19.39 h (h<0.4 m); S=7.88-159 h (h>0.4 m); S=7.88-159 h (h>0.4 m). It is suggested that the pronounced break in slope at 0.4 m is due to a change in the dominant brine drainage mechanism from brine expulsion to gravity drainage. A linear regression for the data collected during the melt season gives <math>S=158+01 h An annual cyclic variation of the mean salinity exists for multi-year sea ice. The mean salinity reaches a maximum at the end of the growth season and a minimum at the end of the melt season.

ICE FORCES ON VERTICAL PILES.

Nevel, D.E., et al, U.S. Army Science Conference, West Point, N.Y., June 20-23, 1972. Proceedings. Vol. III, Washington, D.C., U.S. Army Research and Development Office, 1972, p.104-114, AD-750 358,

Perham, R.E., Hogue, G.B.

SEA ICE, ICE PRESSURE, PILE STRUCTURES.

SEA ICE, ICE PRESSURE, PILE STRUCTURES.

The force that floating ice sheets can exert on vertical piles is important to the design of both military and civilian structures. Present design codes call for 400 psi as the crushing strength of ice without regard to the influencing factors and their variation. The forces which drive the ice into the structure can be water currents, wind, or thermal expansion. These driving forces may be large enough to cause the ice to fail at or near the surface. The purpose of this research is to define this limiting force level and gain a better understanding of the failure process in the ice. (Auth.)

WATER PERCOLATION THROUGH HOMO-GENEOUS SNOW.

Colbeck, S.C., et al, The role of snow and ice in hydrology; proceedings of the Banff Symposia, Sept. 1972, Vol.1, Geneva, Switzerland, WMO-1AHS, Unesco, 1973, p.242-257, With French summary. 7 refs. Includes discussions.

Davidson, G.

29-211 SNOW WATER CONTENT, SNOWMELT, SNOW COVER STRUCTURE, SNOW PERMEABILITY.

The gravity flow theory of water percolation through snow is generalized to include any power law relationship between permeability to the water phase and effective water saturation. Experimental observations of water percolation through homogeneous snow are described. It is found that the exponent in the power law is about 3 for homogeneous snow. The theory is used to construct durinal meltweier waves and these compare favorably with the observed waves. The

differences between the results found for natural snow and those found for repacked snow are discussed The lower limit of applicability of the gravity flow theory is uncertain.

COMPRESSION, COMPRESSIVE ICE. STRENGTH, ICE STRENGTH, SHEAR STRESS, ICE CRYSTALS, MEASURING INSTRUMENTS. ICE CRYSTALS, MEASURING INSTRUMENTS.

An attempt was made to develop a simple but accurate method for making compressive strength tests on right circular cylinders. Compliant loading platens were designed to apply uniform normal stress without introducing significant interface radial shear stresses. The compliant platens gave reproducible results that agree well with results obtained by a precise conventional technique. Accurate results were obtained with simple specimen preparation, and with short specimens where the length-to-diameter ratio was less than unity. Platens were made from a rubber-like urethane which was molded in aluminum cylinders to provide lateral unity. Uniaxial compression tests on cylindrical polycrystalline ice specimens were made to determine the characteristics of the platens. For 21 specimens with ends prepared on a lapping plate to obtain a mirror finish, the measured istics of the platens For 21 specimens with ends prepared on a lapping plate to obtain a mirror finish, the measured strength showed a variation of only 13% for length-to-diameter ratios from 0.74 to 2.5, with no systematic trend. Another 21 specimens with length-to-diameter ratios of about 2.35 were tested with various platens and various methods of specimen end preparation. The strength for specimens with saw-cut ends and for those with ends lapped showed very little difference when tested with the rubber platens

SEA ICE, ICE MECHANICS, ICE STRUCTURE, DRIFT, METEOROLOGICAL FACTORS.

DRIFT, METEOROLOGICAL FACTORS.

The atmospheric circulation which occurred during the Bering Sea Experiment, 15 February to 10 March 1973, in and around the experiment area is analyzed and related to the macroscale morphology and dynamics of the sea ice cover. The ice cover was very complex in structure, being made up of five ice types, and underwent strong dynamic activity. Synoptic analyses show that an optimum variety of weather situations occurred during the experiment an initial strong anticyclonic period (6 days), followed by a period of strong exclonic activity (6 days), followed by a period of strong exclonic activity (3 days), and simily a period of weak exclonic activity (3 days), and simily a period of weak exclonic activity (4 days). The data of the mesoscale test areas observed on the four sea ice option flights, and ship weather, and drift data give a detailed description of mesoscale ice dynamics which correlates well with the macroscale view anticyclonic activity advects the ice southward with strong ice divergence and a regular lead and polynya pattern, cyclonic activity advects the ice northward with ice convergence, or slight divergence, and a random lead and polynya pattern. LAKE ICE, EXPLOSION EFFECTS, ICE BREAK-HP

Operation BREAKUF, FY 66, was a series of small, single Operation BREAKLF, FY 66, was a series of small, single and now charge, chemical explosive detonations fired in fresh water to crater the overlying sheet ice. The experiments were conducted in the winter of 1966 to there feet of ice at Blair Lake, 33 miles SSE of Fa. 3, Alaska. The operation had the following purposes (2) o determine the cratering effects of single and row charges detonated below an ice layer, (2) to study bubble coalescence, and (3) to support theoretical studies of cratering physics. Technical programs included crater measurements, ice surface nical programs included crater measurements, ice surface

motion, engineering properties, and fish surveys Some results and conclusions were: (1) the relationship between depth of detonation and ice crater radius has been defined for 136 pound C4 spherical charges for various experimental conditions; (2) shock wave reflection from the lake bottom did not appear to enhance the crater dimensions; (3) row charge crater dimensions were defined for three charge spacings; (4) cracks appeared to propagate better from larger yield explosions under ice of the same thickness, (5) there did not appear to be any evidence of bubble coelescence in the experiments, (6) commonly used scaling laws may be used to estimate the effects of higher yield ice creating explosions; (7) the procedures used are adaptable to civil application; (8) a detailed evaluation was made of the effects of under-ice explosions on fish, and (9) maintenance of open water gaps created by explosions is affected by refreezing and water currents. Examples of practical engineering applications of the BREAKUP results are included.

TESTS.

The lowa Institute of Hydraulic Research has undertaken model studies on the investigation of ice forces on vertical piles. Model techniques for the study of ice-breaking phenomena have been developed, and the similarity between the model indications and prototype conditions has been demonstrated. Tests on the relationships between ice forces (ice strength) and pile diameter, ice thickness, and relative velocity (strain rate) between ice and structure have been completed. The experimental results were satisfactorily explained by a theoretical approach, and the combination of these relationships led to a basic empirical formula for a circular pile, which agrees with available field measurements and also in part with model investigations in Russia. The suggested formula was modified for application to different structural shapes and degree of contact between ice and structure as well as for application to the indentation case of pile-ice interaction. of prience interaction.

SHELF.

The author comments of the continued existence of the apparently unstable Wes. Antarctic Ice Sheet and Ross Ice Shelf.

The new Feld data on the Ross Ice Shelf and fast moving ice streams obtained by G. Robin (29-3125 or F-14813) is considered essential to the future solution of this geophysical puzzle. It is possible that the West Antarctic Ice Sheet is indeed disintegrating as suggested by T. Hughes (29-0067 or F-12956). A more accurate answer to this question should be obtainable from a three dimensional glacier mechanics analysis carried cut with the aid of computer calculations or with field observations. It is hoped that Robin's data on ice streams may also help to solve the problem of why fast moving ice streams form near the edge of the West Antarctic Ice Sheet.

The soils of the national Tundra Biome sites, which include subantarctic locations, reflect a significantly wide range of soil-forming factors and conditions. It is the purpose of this report to present the most representative set or sets of soil data available for each national project. Presentation of data is confined to the upper three to four soil layers or horizons since these act the most biologically significant for purposes of this volume and other Tundra Biome synthesis activities. The main emphasis here is to provide physical, chemical and thermal soils properties which supplement data presented elsewhere in this volume and which are required for subsequent interpretations of those reports. A hiref summary of major soil conditions at each site is given in order to provide the uninitiated reader with a cursory understanding of the soil physical environment. standing of the soil physical environment

AGERY.

The author has identified the following significant results. ERTS-1 imagery provides a means of distinguishing and monitoring estuarine surface water circulation patterns and changes in the relative sediment load of discharging rivers on a regional basis. Physical boundaries mapped from ERTS-1 imagery in combination with ground truth obtained from existing small scale maps of permafrost terrain and vegetation for the same area. Snowpeck lover within a research watershed has been analyzed and, compared to ground data. Large river icings along the preposed Alaska pipeline route from Prudhoe Bay to the Brooks Range have been monitored. Sea ice deformation and drift northeast of Point Barrow, Alaska have been measured diring a four day period in March and shore-fast ice accumulation and ablation along the west coast of Alaska have been mapped for the spring and early ummer seasons.

THICKNESS, RADIO WAVES

New results about ground conductivity in North Americe became available from gooph, sical studies near Fairbanks, from sites along the Alaska Pipeline and in several areas of the Canadian Arctic: at these locations ground and/or airborne conductivity measurements were made by measuring the waveful and/or the surface impedance of radio ground-waves. The results showed that the ground conductivity in permafrost areas of North America is very heterogeneous, so that it is not directly apparent how to assign an effective conductivity value to a path of practical length (approx. 100 km). The geological and permafrost conditions vary much in Alaska, so that measurements at a location are representative of a small area only, leaving large areas of Alaska open to question. Thereficial evaluations of the seasoial changes in ground conductivity and their effect on radiowave propagation and electrical grounding are also discussed.

ICE DATING, ISOTOPE ANALYSIS, GLACIER ICE.

On several field projects in Greenland, Antarctica and the On several field projects in Greenland, Antarctica and the Swiss Alps, the extraction technique of traces from several trus of ice has been developed and perfected. The procedures are as follows. Surface ice samples are melted in vacuum melt vessels, whereas in bore holes the ice is melted in situ under vacuum at the desired depth. Until now the maximum depth from which samples have been extracted is 780 m. The gasse scaping during the melting process are pumped through a molecular sieve for drying and collection of CO2. The remaining gases are compressed for further treatment in the laboratory Soluble chemistry and collection of CO2. The remaining gases are compressed for further treatment in the laboratory may be carned out either on the melt water pumped to the surface (collection of Si) or down hole by circulating the melt water through ion exchange resins (collection of CO2). The melt water can be filtered for the collection of pollen, terrestrial and cosmic dust Uncontaminated CO2, Ar and Si samples can be obtained for radioisotopic dating. The results of the Si-32 samples allow us to establish an apparent half-life for Si-32 dating. The possible causes of the C-14 variations are discussed and ways to solve the problem suggested. The LANDSAT Parta Collection System (DCS) invides the capability of rapidly collecting hydrologic, meteofologic and environmental data at remote sites throughout the United States and Canada. The coded signals are transmitted via satellite to NASA ground receiving stations where the data are compiled and feletyped to the user. The number of transmissions per day varies considerably depending on the location of each data collection platform (DCP). During the part of the control the location of each data collection platform (OCF). During the past two years, many sensors have been interfaced to the DCP, one of the most important is a porous cup tensiometer.

constructed so that a transducer provides a continuous reading of pore water pressure. Field tests have shown that the transmissions from the DCP are accurate and reliable. This system appears to provide a reliable means of measuring pore water pressure at freeze-up and thaw, critical data needed for validation of current hydrologic models.

MP 1056 GLACIOLOGY'S GRAND UNSOLVED PROB-LEM.

Weertman, J., Mar. 25, 1976, 260(5549), p.284-286. 30-3369

ICE SHEETS, GLACIER OSCILLATION, ICE SHELVES, SEA LEVEL. ICE

Glaciology's grand unsolved problem, or set of interrelated problems, concerns the West Antarctic Ice Sheet, how it Giaciology's grand unsolved problem, or set of interrelated problems, concerns the West Antarctic Ice Sheet, how it formed, whether it it growing or disintegrating, why fast moving ice streams form at its periphery, etc. Geological evidence indicates that before 10,000 yr ago the West Antarctic Ice Sheet was much larger, covering the area, now below sea level, presently occupied by the Ross Ice Shelf and that a large scale retreat took place at its edge. The retreat was probably caused by the large rise in sea level that occurred when the ice sheets in the northern hemisphere melted at the end of the last ice age. It has been suggested that the West Antarctic Ice Sheet is still disintegrating, its edge retreating where it joins the Ross Ice Shelf on the order of 70 m/yr. This slowly occurring destruction could account for the present rate of rise of the mean sea level Recent data collected on the Ross Ice Shelf reaches the startling conclusion that the position of the edge of the ice sheet at least at one location is advancing at the very fast rate of 1 km/yr. Extensive field data will be required to determine whether the ice sheet is disintegrating or growing and at what rate.

MP 1059 TECHNIQUES FOR USING LANDSAT IMAGE-RY WITHOUT REFERENCES TO STUDY SEA ICE DRIFT AND DEFORMATION.
Hibler, W.D., III. et al, Mar. 1976, No.31, p.115-135.

Tucker, W.B., Weeks, W.F. 30-3888

SEA ICE, DRIFT, ICE DEFORMATION, POSITION (LOCATION), LANDSAT.

TION (LOCATION), LANDSAT.

A semi-automatic procedure is described for transferring ice coordinates rapidly and accurately from one LANDSAT image to another and for simultaneously estimating all linear inceasures of the ice deformation. The procedure takes into acci int the non-parallel nature of the longitude lines and the finite curvature of the latitude lines, factors which are particularly critical in the polar regions. Necessary inputs are the location coordinates (latitude and longitude) of the entire of each inceasured the location of the control o of the center of each image and the location of two arbitraty points on a line of longitude on the image. These equations, which are valid over distances of several hundred kilometers. by pass the complex and time-consuming procedure of projecting points on the spheroid. After the transfer of common ree feature locations (on successive days) is completed, a least squares program yields the average strain rate and vorticity, with the strain rate being independent of errors in the transfer of the coordinate system. Transfer, vorticity, and strain rate errors of the technique are described.

ICE SHELVES, ICE CORING DRILLS, DRILL-ING, ANTARCTICA—ROSS ICE SHELF.

ING, ANTARCTICA—ROSS ICE SHELF.

The wire line core drilling system used for the Ross lee Shell Project and the problems encountered in using the equipment are described. The proposed plans included drilling four holes: the water well hole. Bern hole, ecre hole, and access hole. The generally unsuccessful operations during the season indicated that it is not feasible to drill an open hole through the Ross lee Shelf due to closure of the drilled hole as a result of the flowing characteristics of see. of ice.

CONCENTRATED LOADS ON A FLOATING ICE

Nevel, D.E., 1977, 19(81), p.237-245, In English with French and German summaries. 8 refs.

FLOATING ICE, ICE BEARING CAPACITY, TENSILE STRESS, ICE ELASTICITY, LOADS (FORCES), ICE COVER THICKNESS, MATH-EMATICAL MODELS.

The safe bearing capacity of a floating ice sheet is usually determined by limiting the maximum tensile stress which occurs under the load at the bottom of the ice sheet. If the size of the load distribution is large compared to the ice thickness, the thin plate theory predicts these stresses correctly. However, if the size of the load distribution becomes small compared to the ice thickness, the plate becomes small compared to the ice thickness, the plate theory overestimates the stresses. In this case the ice sheet should be treated as a three-dimensional elastic layer. Previous investigators have solved the elastic-layer problem for loads distributed over a circular area, and have limited the results to the stress at the bottom of the ice sheet directly under the center of the load. In the present paper the stresses are evaluated at any radial position, and it is shown how these stresses approach those for the plate theory as the radial position becomes large. The solutions for the stresses are presented in integral form, as well as graphs from the numerical integration. These new results are significant for the superposition of stresses when two concentrated loads act near each other. Similarly for loads distributed over a rectangular area, the plate theory will overestimate the stresses if the dimensions of the load will overestimate the stresses if the dimensions of the load become small compared to the ice thickness For this case integral solutions are presented for the stresses, and are evaluated directly under the center of the load. MP 1063 FLEXURAL STRENGTH OF ICE ON TEMPER-ATE LAKES.

Gow, A.J., 1977, 19(81), p 247-256, In English with French and German summaries. 7 refs.

FLEXURAL STRENGTH, LAKE ICE, ICE CRYS-TAL STRUCTURE. TENSILE STRESS, ICE CRACKS, TESTS.

Large, simply supported beams of temperate lake ice generally yield significantly higher flexural strengths than the same beams tested in the cantilever mode. Data support the view that a significant stress concentration may exist at the fixed corners of the cantilever beams. Maximum effects are experienced with beams of cold, brittle ice substantially described by the control of the cantilever of the control of the contro are experienced with beams of cold, brittle ice substantially free of structural imperfections, the stress concentration factor may exceed 20 in this kind of ice. In ice that has undergone extensive thermal degradation the stress concentration effect may be eliminated entirely. Simply supported beams generally test stronger when the top surface is placed in tension. This behavior is attributed to differences in ice type, the fine-grained, crack-free top layer of snow-ice usually reacting more strongly in tension than the coarse-grained bottom lake ice which is prone to cracking. ICE REMOVAL, PNEUMATIC EQUIPMENT, ICE DETECTION, ICE NAVIGATION.

A rough comparison between thermal and mechanical methods A rough comparison between thermal and mechanical methods of de-teng indicates that mechanical methods could potentially desice with an order-of-magnitude less energy than that required to melt an ice accretion. Two applications of mechanical desicing using pneumatically driven inflatable desicers are described in this report. The first of these was the descript of a small cylindrical radome used for air margational purposes. Two sersons of testing were conducted with a desicer consisting of an inflatable-defiatable flexible plattic covering. The desicer was driven by tanks with pressure and vacuum reservoirs that were recharged by an on-site air compressor in response to a pressure sensor on-site air compressor in response to a pressure sensor. The descring cycle was activated by an ice detector so the system responded to long events on a demand basis driven by the ice detector. The system proved successful in keeping the radome free of ice without manned operation. small energy consumption in a mountain teing ent. The second application was an attempt to

de-ice the walls of locks used in river navigational facilities. Ice usually formed at the high-water-mark by the freezing of the water exposed to low air temperatures or by the pressing of ice against the walls by thips using the locks. The de-icers consisted of air-driven hoses mounted on the wall covered by a thick flexible rubber mat and protected from ship damage by steel outer plates. This method was successful in removing ice accumulations up to 2 m long by 0.3 m thick over the area covered by the de-icer. Installation costs and the necessity for protection of the de-icer against abrasion by ships may make this de-icing method prohibitively expensive compared with methods which are not as susceptible to damage by ships (e.g., chemical coating and electrical heating cables buried in the walls).

ICE SHELVES, ICE STRUCTURE, ICE MECHANICS, ICE FRICTION, ICE THERMAL PROPERTIES, ICE ELECTRICAL PROPERTIES, ICE (CONSTRUCTION MATERIAL), ENGINEERING, SEA ICE, ICE STRENGTH.

(CONSTRUCTION MATERIAL), ENGINEER-ING, SEA ICE, ICE STRENGTH.

As the continental shelves of the Arctic become important as source areas for the oil and minerals required by human society, sea ice becomes an increasing challenge to engineers. The present paper starts with a consideration of the different fields of engineering which require information on sea ice with the tasks ranging from the design of ice-breaking ships to Arctic drilling platforms and man-made ice islands. Then the structure of sea ice is described as it influences the observed variations—physical properties. Next the status of our knowledgr—the physical properties important to engineering is reviewed. Properties discussed include mechanical properties (compressive, tensile, shear and flexural strengths; dynamic and static clastic moduli; Poisson's ratio), friction and adhesion, thermal properties (specific and latent heats, thermal conductivity and diffusivity, density) and finally electromagnetic properties (dielectric permittivity and loss, resistivity). Particular attention is given to parameters such as temperature, strain-rate, brine volume, and loading direction as they affect property variations. Gaps, contradictions in the data, and inadequacies in testing techniques are pointed out. Finally suggestions are made for future research, especially for more basic laboratory studies dasigned to provide the data base upon which further theoretical developments as well as field studies can be built. MP 1066 STUDIES OF THE MOVEMENT OF COASTAL SEA ICE NEAR PRUDHOE BAY, ALASKA, U.S-

Weeks, W.F., et al, 1977, 19(81), p.533-546, In English with French and German summaries. 5 For this paper from another source see 31-2777. Kovacs, A., Mock, S.J., Tucker, W.B., Hibler, W.D., III, Gow, A.J.

32-2471 FAST ICE, PACK ICE, ICE MECHANICS, THER MAL EXPANSION, RADAR TRACKING, LAS-ERS, SEA ICE, ICE CONDITIONS, UNITED STATES—ALASKA—PRUDHOE BAY.

STATES—ALASKA—PRUDHOE BAY.

During March-May 1976, a combination of laser and radar ranging systems was used to study the motion of both the fast ice and the pack ice near Narwahl and Cross Islands, two barrier islands located 16 and 21 km offshore in the vicinity of Prudhoe Bay, Alaska Laser measurements of targets on the fast ice near Narwahl Island indicate small net displacements of approximately 1 m over the period of study (71 d) with short-term displacements of up to 40 cm occurring over 3 d periods. The main motion was outward normal to the coast and was believed to be the result of thermal expansion of the ice. The radar records of fast-ice sites farther offshore show a systematic increase in the standard deviation of the displacements as measured parallel to the coast, reaching a value of 6 6 m increase in the standard deviation of the displacements as masured parallel to the coast, reaching a value of 66 m at 31 km. The farthest fast-ice sites show short-term displacements of up to 12 m. There are also trends in the records that are believed to be the result of the general warming of the fast ice with time. Radar targets located on the pack ice showed large short-term displacements (up to 2.7 km) but negligible net ice drift along the coast. There was no significant correlation between the movement of the pack and the local wind, suggesting that coastal ice prediction models can only succeed if handled as part of a regional model which incorporates stress transfer through the pack. The apparent fast-ice-pack-ice boundary in the study are was located in 30-35 m of water. (Auth)

MP 1067 SHORT-TERM FORECASTING OF WATER RUN-OFF FROM SNOW AND ICE.
Colbeck, S.C., 1977, 19(81), p.571-588, In English

with French and German summaries. Refs. p.585-587.

32-2474 RUNOFF FORECASTING, SNOW HYDROLOGY, ICE MELTING, SNOW MELTING, GLACIAL HYDROLOGY, MELTWATER, SNOW COVER EFFECTS. MODELS

Accurate forecasting of water run-off from snow covers and glaciers is increasingly important because of the increasing competition for scarce water resources. The trend toward conceptual computerized models of hydrologic systems requires extensive knowledge of the physical aspects of those systems. Unlake river and stream networks, the hydrological characteristics of snow covers and glaciers are highly variable with time and cannot be easily defined. After reviewing the physical aspects of water flow through snow covers and glaciers, it is concluded that snow covers and glaciers are predictable hydrological systems once the melt metamorphism of the snow is complete and the englacial conduits have been established. However, much additional information about snow and ice masses must be generated before general forecasting techniques can be established for all situations. (Auth.)

ALASKA—NORTH SLOPE.

The U.S. Army Cold Regions Research and Engineering Laboratory (USA CRREL) has long conducted research in snow, ice, and permafrost. It also translates foreign language engineering papers and publishes research reports, monographs, and bibliographies. Snow and ice roads and construction pads have been used, primarily on the Arctic Slope, during the last few winters. Some have been successful but problems exist which will require further experience and research to solve. One problem is that of snow supply. Snowfall on the Arctic Slope is limited, particularly early in the season when it is most desired. Few good data are available on total quantities and the time pattern of snowfall but Wyoming Snow Gages, now being installed by a number of government agencies and private organizations, are beginning to provide some data which can be used with some confidence. The snow which falls is often blown off by the strong winds which are common in the area so it is not available where it is needed. Research is under way on equipment and techniques for collecting snow and inducing drifting.

FLOATING ICE, REMOTE SENSING, SENSOR MAPPING, AERIAL RECONNAISSANCE, SEA-SONAL VARIATIONS.

SONAL VARIATIONS.

The current increase of scientific interest in all forms of fe.s.ing ice—sea ice, lake ice, river ice, ice shelves and icebergs—has occurred during a time of rapid evolution of both remote-sensing platforms and sensors. The application of these new research tools to ice studies in the Arctic and Antarctic has generally been both piecemeal and sporadic, partly because the community of ice scientists has not kept up with the rapid advances in remote sensing technology and partly because they have not made their needs known to the space community. This paper seeks to help remedy the latter shortcoming. The remote sensing requirements for floating ice studies are given, and the capabilities of various existing and future sensors and sensor combinations in meeting these requirements are discussed. The desirable future sensors are also discussed from both the research and operational points of view.

MP 1070 DYNAMICS OF SNOW AVALANCHES.

Mellor, M., Rockslides and avalanches, 1. Natural phenomena. Edited by B. Voight, New York, Elsevier, 1978, p.753-792, 22 refs.

AVALANCHE MECHANICS, SNOW COVER STABILITY, SHEAR STRAIN, AVALANCHE

WIND.

After a general introduction to snow avalanches and their consequences, type classification is discussed, and classification schemes are described briefly. The first technical section deals with deformation and displacement of snow slopes prior to avalanche release, with the failure process, and with the propagation of initial failure. The following section describes various types of avalanche motion after release. Representative values are suggested for slope angles, initial accelerations, flow density, driving stresses, and travel velocities. The third technical section considers idealized theoretical analyses of avalanche motion. The final technical tes The third technical section constitutes are analyses of avalanche motion. The final technical section covers the dynamic forces imposed by snow avalanches

and their associated "winds." Measured values of impact stresses are summarized, and direct impact stresses for "wide" avalanches are deduced from simple theory. Forces induced by interfacial shear and avalanche deflection are considered briefly, and forces created by avalenche winds, or "air blast," are discussed. In the conclusion there is a simplified tabulation of representative values for stress ranges, typical strain rates and typical velocities in the various avalanche

IN-SITU MEASUREMENTS ON THE CONDUCTIVITY AND SURFACE IMPEDANCE OF SEAICE AT VLF FREQUENCIES.

SEA ICE. ICE RESISTIVITY, ELECTRICAL RESISTIVITY.

RESISTIVITY.

An experimental program to measure in-situ values of the electrical conductivity and surface impedance of sea ice at VLF frequencies was carried out at Pt. Barrow, Alaska. Temperature, salinity, and resistivity were measured as a function of depth in the ice for both first year and multi-year sea ice by means of cored samples. All three quantities varied with the age of the ice and, in addition, the resistivity varied with age from 100 to 10,000 ohm-meters at the surface, and in general down to a few ohm-meters at the sea water interface. The wave tilt of a VLF plane wave propagating over sea ice is theoretically linearly dependent on the thickness. Measurements of the quadrature phase wave tilt at 18.6 KHz give values of the right order of magnitude but erratic in local behavior. Short-spacing Wenner array resistivity measurements and tellizic current measurements at VLF demonstrated that the erracic behavior was due to significant horizontal variations of the sea ice resistivity over distances of a few feet.

NEERING.

The overall objectives of the CRREL participation in the subsea permafrost program are to quantify the engineering characteristics and ascertain the distribution of permafrost beneath the Beaufort Sea and to determine their relationship to temperature, sediment type, ice content and chemical composition. Permafrost was pres;n' in the four holes drilled at Prudhoe Bay. Ice bonder, permafrost was absent in the upper 30 meters of sediment up to 17 k.lometers from shore. Based on negative temperature gradients and pore water chemistry, ice-bonded permafrost should be encountered at 30- and 43-meter depths at sites PB-2 and PB-3, respectively. It appears that the depth to the ice-bonded permafrost decreases with increasing distance from shore and depth of water. Highly over-consolidated marine clays were encountered seaward of keindeer Island. The overconsolidation probably resulted from the freeze-thaw history. The presence of these stiff, matrice clay deposits is an in portant consideration for siting structures associated with offshore developments.

TICA—ROSS ICE SHELF.

The scientific objectives of the Ross Ice Shelf Project (RISP) are to drill into the ice shelf to investigate the physical, chemical, biological, and geological conditions in 're ace shelf, the water mass beneath the ace, and the soft sediments and bedrock at the bottom of the sea, and to use the data obtained for interpretation of the present conditions and the history of this portion of Antarctica. This environmental impact assessment describes the proposed action, summarizes the scientific studies to be undertaken, and outlines remedial and protective measures, unavoidable adverse impacts, and alternatives to the proposed action. It is anticipated that the majority of the impacts will be short-term and extremely localized, such as those associated with the camp and laboratory facility on the Ross Ice Shelf during the period of drilling. These impacts will be monitored throughout the RISP operations. The pristine nature of the surface should be restored fully within one year. It is stressed that the likelihood of penetrating a hydrocarbon trap is remote, but should this occur rendering an uncontrollable release of hydrocarbons, the impact on the environment could be quite severe On a scale of 1 to 10 this possibility is assigned a value of 5. is assigned a value of 5.

CLE SIZE DISTRIBUTION.

The permeability and structure of four fine-grained soils were observed to be changed by freezing and thawing. In all cases freezing and thawing caused a reduction in void ratio and an increase in vertical permeability. The increase in permeability is attributed to the formation of polygonal shrinkage cracks and/or to the reduction of the volume of fines in the porces depending on material type. No definite relationships are established; however, it appears that the largest increase in permeability occurs for the soil of highest plasticity. of highest plasticity.

FOUNDATIONS, SOIL TEMPERATURE.
Construction of the hospital was started in late 1959 and completed in September 1961. The hospital is a single-story structure, supported on insulated perimeter wall footings, with intermediate footings for the support of roof columns and grade beams. All floors are slab-on-grade concrete. Wall cracking was in evidence in the first year of occupancy. A void of more than a foot was found between the floor slab and the gravel fill in August, 1963. At the request of the U.S. Public Health Service, USA CREEL conducted soil explorations and installed ground temperature assemblies and vertical movement points within the building and around the perimeter of the foundation to ascertain the source and potential magnitude of the foundation distress. The performance of the hospital through 1976 clearly indicates the settlement associated with the thawing of the underlying permafrost with time. Soil and permafrost conditions in the village of Kotzebue are described in light of the conditions disclosed in the hospital area.

EFFECTS OF MOISTURE AND FREEZE-THAW ON RIGID THERMAL INSULATIONS: A LABORATORY INVESTIGATION.

Kaplar, C.W., Conference on Applied Techniques for Cold Environments, Anchorage, Alaska, May 17-19, 1978. Proceedings, Vol.1, New York, American Society of Civil Engineers, 1978, p.403-417, 13 refs. 32-3628

THERMAL INSULATION, ABSOMOISTURE, FREEZE THAW TESTS. ABSORPTIVITY,

MOISTURE, FREEZE THAW TESTS.

Laboratory observations on the effects of moisture absorption and freeze-thaw on various thermal insulation boards commonly used in construction beneath slabs on grade, in toofs, and in perimeter insulation of foundations were made under wet conditions. Test specimens were submerged in water and buried in mosts soil for periods ranging up to 36 months. Selected soaked specimens submerged in water were subjected to 15 and 30 freeze-thaw cycles. The study showed that:

1) None of the materials was completely resistant to moisture absorption under all test conditions, 2) A number of extruded polystyrenes were highly resistant to moisture, 3) The beaded polystyrenes were highly resistant to moisture. 3) The beaded polystyrene boards were more absorbent than the extruded types, and 4) Alternate freezing and thawing of rigid insulation polyasyrene boards were more absorbent than the extruded types, and 4) Alternate freezing and thawing of rigid insulation in presence of free water was either destructive or increased moisture absorption in most of the tested materials, and 5) Cellular glass, normally highly moisture resistant in soaking tests, suffered extremely severe deterioration in freeze-thaw tests. This study clearly demonstrated that only highly moisture-resistant rigid thermal insulations should be used under conditions subject to free water and alternate freezing and thawing.

DESIGN CONSIDERATIONS FOR AIRFIELDS IN NPRA.

Crory, F.E., et al., Conference on Applied Techniques for Cold Environments, Anchorage, Alaska, May 17-19, 1978. Proceedings, Vol. 1, New York, American Society of Civil Engineers, 1978, p.441-458, 6 refs. Berg, R.L., Burns, C.D., Kachadoorian, R. 32-3631

AIRCRAFT LANDING AREAS, FROZEN SAND, FROZEN GRAVEL, PETROLEUM INDUSTRY. Two exploratory wells, at lindgok and Tunalik, will be spudded in the spring of 1978. The well sites require airfields for Hercules aircraft during the entire drilling operation Design and construction problems for the two airfields are compounded by the constraint that they be built in winter and in accordance with environmental requirements which necessitate that all fill and gravel be transported over snow roads. Laboratory studies conducted at USACRREL showed that fills of frozen silty sand, the only locally available borrow at Inagok, have a greater potential for settlement upon thewing than the in-situ sands in cut sections. Several design options were considered for the airfields. deill nade seen thewing Can the in-situ sands in cut sections. Several design options were considered for the airfields, drill pads and short connecting roads which must be usable all year. These included (1) gravel over sand, (2) gravel over insulation as and, (3) landing mat with insulation, and (4) landing mat without insulation. Some of these concepts were evaluated at USAEWES, using large-scale test sections. In conjunction with the airfields, additional test sections are planned to evaluate different design concepts for runways, drill pads and roads to be built for the 1979 drilling program. This paper describes studies associated with the Inigok airfield. MP 1087

EFFECTS OF SUBGRADE PREPARATION UPON FULL DEPTH PAVEMENT PERFORMANCE IN COLD REGIONS.

Eaton, R.A., Conference on Applied Techniques for Cold Environments, Anchorage, Alaska, May 17-19, 1978. Proceedings, Vol.1, New York, American Society of Civil Engineers, 1978, p.459-473, 8 refs. 32-3632

BITUMINOUS CONCRETES, COLD WEATHER PERFORMANCE, SUBGRADE PREPARATION, FROST HEAVE.

FROST HEAVE.

In September, 1973, a "full-depth" road test section was constructed at the U.S. Army Cold Regions Research and Engineering Laboratory (CREEL), Hanover, New Hampshire. Due to weather and time constraints, the subgrade beneath the asphalt concrete pavement was not properly prepared (blended, mixed, and made as uniform as possible) The road is in a cut area on an 87 slope and intersects horizontal layers of varved silts, silty sands, and sandy materials which are highly frost susceptible. The first winter, surface differential heaves of up to 5 inches in 5 feet occurred. The following summer, the subgrade was removed for 100 feet to a depth of 24 inches and 100 feet to a depth of 12 inches. The material was mixed, blended, and dried before placing back into the roadway in 6-inch compacted lifts. The succeeding two winters' performance has shown very marked improvement with relatively uniform heaving of the pavement surface. This shows, in conjunction with other CRREL highway pavement test sections, the importance of proper subgrade preparation for pavements in cold regions over frost-susceptible soils.

MP 1988 STORM DRAINAGE DESIGN CONSIDERA-TIONS IN COLD REGIONS.

Lobacz, E.F., et al, Conference on Applied Techniques for Cold Environments, Anchorage, Alaska, May 17-19, 1978. Proceedings, Vol.1, New York, American Society of Civil Engineers, 1978, p.474-489, 12 refs. 32-3633

DRAINAGE, AIRCRAFT LANDING AREAS, ICE

DRAINAGE, AIRCRAFT LANDING AREAS, ICE CONTROL, COLD WEATHER OPERATION.

This paper, based on the authory' recently revised design manual for drainage facilities at Army and Air Force airfields and heliports, adapts previously used U.S. hydraulic design criteria it. the special conditions prevailing in arctic and subarctic regions. Design runoff supply rates for surface drainage are derived from rainfall plus snowmelt minus infiltration, three factors for which typical values are given, for both permafrost and unfrozen ground situations. Guidelines are discussed for other drainage design requirements such as structural, durability, maintenance, and, of major significance in cold regions, environmental impact considerations and debtis and icing control Because of the importance of control and prevention of icings in and near drainage structures, applicable principles formulated by CRREL and other researchers are enunciated. While primarily intended for design of storm drain pipes, appurtenances and open drainage ditches serving airfields and heliports, the principles outlined are also generally suitable for culverts and drainage for facilities such as roadways, parking lots, and built-up areas in the Arctic and Subarctic.

TECHNIQUES FOR USING MESL (MEMBRANE ENCAPSULATED SOIL LAYERS) IN ROADS AND AIRFIELDS IN COLD REGIONS. Smith, N., Conference on Applied Techniques for Cold Environments, Anchorage, Alaska, May 17-9, 1978. Proceedings, Vol.1, New York, American Society of Civil Engineers, 1978, p 560-570, 15 cfs. 32-3640

SOIL TEXTURE, SOIL WATER, SOIL COMPAC-TION, WATERPROOFING, LAYERS

TION, WATERPROOFING, LAYERS
Membrane encapsulation of fine-grained soils to prevent soil
moisture intrusion can provide an option to the use of
more eapensive select granular soils as structural layers in
roads and airfields, even in cold regions. Silts and clays
compacted at, or slightly below, optimum moisture contents
can provide high bearing strengths and are not subject to
moisture migration or detimental firost heaving during closed
system (membrane encapsulated) freezing. Central Alaska
has an abundant supply of silts, and the semi-arid climate
is ideal for air-drying those that have an in-situ moisture
content above optimum. In other areas it might not be
economically or technically feasible to dry the soils to the
required moisture content for encapsulation unless granular
soils are extremely scarce.

32-3817 ICE COMPOSITION, CHEMICAL ANALYSIS, ICE CORES, GREENLAND.

Chemical analysis for Na, Cl, Al, Mn and V of surface snows and deeper uce core samples from station Milcent, Greenland, indicates a terrestrial or marine origin for these constituents. Pre-1900 enrichment factors, based on average Greenland, indicates a terrestrial or marine origin for these constituents. Pre-1900 enrichment factors, based on average crustal composition, are high for Zn and Hg and appear to be related to the volatility of these elements. A comparison of pre-1900 and 1971-1973 concentrations of V and Hg shows no decided increase due to industrial production, yet the relative abundance of Zn increased from 12 to 32 over this time period. The chemical composition of ancient ice is extremely useful in interpreting modern aerosols.

TRACER MOVEMENT THROUGH SNOW.

Colbeck, S.C., 1977, No.118, International Symposium on Isotopes and Impurities in Snow and Icc, Grenoble, Aug. 28-30, 1975, p.255-262, In English with French summary. 19 refs.

32-3840 SNOW COMPOSITION, MOISTURE TRANSFER. IMPURITIES.

Impurities flowing with water through snow undergo hydrody-namic dispersion. Solutions describing the distribution of impurities are hard to obtain for realistic boundary conditions. The movement of impurities in snow is approximated here by neglecting second-order effects on their movement.

SEASONAL VARIATIONS OF CHEMICAL CONSTITUENTS IN ANNUAL LAYERS OF GREENLAND DEEP ICE DEPOSITS.

Langway, C.C., Jr., et al, 1977, No.118, International Symposium on Isotopes and Impurities in Snow and Icc, Grenoble, Aug. 28-30, 1975, p 302-306, In English with French summary. 13 refs. Klouda, G.A., Herron, M.M., Cragin, J.H.

32-3846

ICE CORES, CHEMICAL ANALYSIS, SEASON-AL VARIATIONS, ICE DATING.

Chemical analysis of century-old ice from continuous 5-year intervals of three ice cores obtained from south and central Greenland (Dye 3, Milcent and Créte) shows max-imum concentrations of Na, Mg. Ca. K and Al during early spring and minimum concentrations during late summer and early fall. Peak spring values are as much as 10 times greater than fall values. Because of the large seasonal chemical variations, samples used for depth-age or annual deposition rate stud-ies must represent exactly one (or multiple) year's accumulation. The seasonal chemical variations seem promising as a new method of defining annual layers and thus dating old ice

THERMAL PROPERTIES AND REGIME OF WET TUNDRA SOILS AT BARROW, ALASKA.

McGaw, R., et al, International Conference on Perma frost, 3rd, Edmonton, Alberta, Canada, July 10-13, 1978. Proceedings. Vol.1, Ottawa, National Research Council of Canada, 1978, p.47-53, With Russian and French summaries. 12 refs. Outcalt, S.I., Ng. E.

TUNDRA SOILS, THERMAL CONDUCTIVITY, TUNDRA VEGETATION, SOIL TEMPERATURE, TEMPERATURE MEASUREMENT.

TURE, TEMPERATURE MEASUREMENT.

Measurements of temperature and of thermal conductivity for two summer periods were carried out on wet organic surface materials and underlying mineral soils at Barrow, Alaska. Precise temperatures were measured by means of calibrated thermistors placed at accurately known depths, from which temperature gradients to a depth of 1.0 m are calculated. Thermal conductivities were measured by the transient-heating probe method, both in-situ and in the laboratory. The observed conductivity of the organic layer was between that of moist air (0.1 W/mK) and that of water (0.6 W/mK); the conductivity of the silt soil depended on the state of freezing. The measured data are combined to calculate summer heat fluxes to a depth of 1.0 m, from which the thermal transition of the active layer from initial thaving to incipient freezing is described and analyzed. thawing to incipient freezing is described and analyzed.

DETERMINATION OF UNFROZEN WATER IN FROZEN SOIL BY PULSED NUCLEAR MAG-VETIC RESONANCE.

Trice, A.R., et al, International Conference on Perma-frost, 3rd, Edmonton, Alberta, Canada, July 10-13, 1978. Proceedings. Vol.1, Ottawa, National Re-search Council of Canada, 1978, p. 149-155, With Rus-sian and French summaries. 12 refs.

FROZEN GROUND, GROUND ICE, UNFROZEN WATER CONTENT, MEASURING INSTRU-MENTS.

Pulsed nuclear magnetic resonance (NMR) techniques have Pulsed nuclear magnetic resonance (NMR) techniques have been developed and utilized to determine complete phase composition curves for three soils. This promising new technique offers a non-destructive method for measurements of unfrozen water contents in frozen soils from -0.2C through -25C. The results show that unfrozen water contents determined by this technique depend upon ice content (i.e. total water content). These results are contrary to earlier assumptions based on results which indicated that unfrozen water contents are a function of temperature only. These water contents are a function of temperature only These findings show great promise in the discrimination of unfrozen water associated with mineral grain boundaries and the icewater interfaces of the poly-crystalline ices present in soilwater syrtems

MP 1098 GEOECOLOGICAL MAPPING SCHEME FOR ALASKAN COASTAL TUNDRA.

Everett, K.R., et al, International Conference on Permafrost, 3rd, Edmonton, Alberta, Canada, July 10-13, 1978. Proceedings. Vol.1, Ottawa, National Research Council of Canada, 1978, p. 359-365, With Russian and French summaries. 8 refs. 17.1717

TUNDRA, MAPPING, CHARTS, VEGETATION PATTERNS, TUNDRA SOILS, UNITED STATES -ALASKA.

A unified geoecological mapping system has been developed for northern Alaska which recognizes in a given area a suit of landforms whose geomorphic elements control the composition and distribution of vegetation and soil. Within composition and distribution of segetation and soil Within each landform boundary a fractional code is displayed in which the numerator consists of the geomorphic feature and its characteristic segetation stand presented as a series of alpha-numeric units. The denominator is comprised of three elements the soil(s), the landform type and its mean slope Each map contains an annotated list of code symbols and is accompanied by a text in which the characteristics of the code components are discussed. The advantages of such a mapping technique include: (1) integrating on a single base a large body of diverse data into a relatively few easily detected environment units, (2) the denvation of any number of special purpose maps by selecting components of the cod and/or related analytical data; (3) permitting an expansion of the code to include other kinds of geotechnical

CLIMATIC AND DENDROCLIMATIC INDICES IN THE DISCONTINUOUS PERMAPROST ZONE OF THE CENTRAL ALASKAN UPLANDS. Haugen, R.K., et al, International Conference on Permafrost, 3rd, Edmonton, Alberta, Canada, July 10-13, 1978. Proceedings. PERMAFROST DISTRIBUTION, DISCONTINU-OUS PERMAFROST, ALPINE TUNDRA, TUN-DRA VEGETATION, FOREST TUNDRA, PLANT ECOLOGY, CLIMATIC FACTORS, UNITED STATES—ALASKA—CENTRAL ALASKAN UP-LANDS.

Most climatic records from central Alaska represent lowland sites. Consequently, continuous climatic observations were initiated in 1970 at four sites (750-1150 m clevation) 160 km north of Fairbanks near Eagle Summit, at one site (1040 m) to km east of Livengood, and at one site (1040 m) on the northern flank of Mt. Fairplay. Mean annual temperatures at these upland sites range from -8.1 to -6.4C, as compared to -3 5C at Fairbanks for the same period of record. The site data characterize air temperatures and permafrost conditions for several different alpine tundra and forested settings. Based upon correlations of radial growth of timberline white spruce and June-July temperatures, dendroclimatic patterns of warm and cool growing seasons are documented over the past 300 years for the Yukon-Tanins Uplands. Similar timberline tree growth patterns are found south to the Alaska Range and at the white spruce timberline in the southern foothills of the Brooks Range, suggesting a relative uniformity of summer temperature patterns throughout central Alaska.

BIOLOGICAL RESTORATION STRATEGIES IN RELATION TO NUTRIENTS AT A SUBARCTIC SITE IN FAIRBANKS, ALASKA.

Johnson, L.A., International Conference on Perma Jonnson, L.A., International Conference on Perma-frost, 3rd, Edmenton, Alberta, Canada, July 10-13, 1978. Proceedings. Vol.1, Ottawa, National Re-search Council of Canada, 1978, p.460-466, With Rus-sian and French summaries. 9 refs. 32-3732

SUBARCTIC LANDSCAPES, ARCTIC LAND-SCAPES, ENVIRONMENTAL PROTECTION, REVEGETATION, UNITED STATES—ALASKA -FAIRBANKS.

Restoration needs in the far north have dramatically increased as the extent of surface disturbance has increased over the last decade. The urgency of arctic and subarctic revegetation and restoration has prompted the use of technology developed in the temperate zones, at least some of which may ultimately be suitable in these colder regions. A randomized block design was established in 1975 on the Chena Flood Control Project in order to test the effect of nutrient applications upon the competitive relationships between arctared fescue, bluepoint reedgrass, and annual rye. Data gathered over two growing seasons on biomass, cover, maximum height, nutrient content, and other pertinent parameters are used to predict the effects of nutrient manipulation upon long-term restoration goals. It is anticipated that this research will increase the options available for successful mitigation of impact from northern industrial development.

PRUDHOE BAY.

An environmental engineering study including the \$8 kilometer TAPS Road and the \$80 kilometer Alyeska Pipeline Haul Road was initiated during the summer of 1976. Physiography along the route ranges from the rolling Yukon-Tanana Uplands, where the permafrost is warm (-1 C) and discontinuous, through the Brooks Range and the Arctic Foothills to the Arctic Coastal Plain, where permafrost is cold (-1 C) and continuous. Permanently frozen subgrade materials range from rock to externely ice-rich fine-grained sitis. Approximately 30 sites have been selected for measuring thaw subsidence and seasonal thaw penetration, instrumentation for measuring air temperatures were also measured at three of these sites. The 1976 thawing indexes varied from 350C degree-days at Prudhoe Bay to 1840C degree-days at Livengood. Measured thaw penetration in undisturbed areas adjacent to the road varied from 28 cm to 112 cm. The calculated gravel embankment thickners to prevent subgrade thawing during the 1976 thawing season ranged from 1.9 m near Prudhoe Bay to 5.2 m near Livengood.

DENSIFICATION BY FREEZING AND THAW-ING OF FINE MATERIAL DREDGED FROM

WALERWAYS. Chamberlain, E.J., et al, International Conference on Permafrost, 3rd, Edmonton, Alberta, Canada, July 10-13, 1978. Proceedings. Vol.1, Ottawa, National Re-search Council of Canada, 1978, p.622-628, With Rus-sian and French summaries. 11 refs.

32-3755

DREDGING, SOIL COMPACTION. FREEZE THAW CYCLES.

FREEZE THAW CYCLES.
Volume changes and permeabilities for fine material dredged from waterways were observed in the laboratory after full consolidation and freeze-thaw cycling for applied pressures in the range of 0.93 to 30.73 kN/sq m. Up to 20% volume reduction was observed when dredged materials with liquid limits in the range of 60 to 92% were subjected to freeze-thaw cycling. Vertical permeabilities were observed to increase by as much as two orders of magnitude. The technical and economic feasibility of using freeze-thaw overconsolidation procedures to increase the volume of material stored in disposal sites is considered.

ENGINEERING PROPERTIES OF SUBSEA PERMATROST IN THE PRUDHOE BAY RE-GION OF THE BEAUFORT SEA.

Chamberlain, E.J., et al, International Conference on Permafrost, 3rd, Edmonton, Alberta, Canada, July 10-13, 1978. Proceedings. Vol.1, Ottawa, National Research Council of Canada, 1978, p 629-635, With Russian and French summaries. 14 refs.

SUBSEA PERMAFROST, DRILLING, DRILL CORE ANALYSIS, FROZEN ROCK TEMPERA-TURE, BEAUFORT SEA.

TURE, BEAUFORT SEA.

Core samples, cone penetration resistance and temperature data obtained from subsea sediments near Prudhoe Bay. Alaska, provided the basis for this study. The sites were located 1 to 17 km from shore in 2 to 12 m of water Maximum hole depth was 50 m. The materials at the drill sites included sands and gravels overlain by 45 to 5 m of silts and clays. No ice-bonded materials were observed, although thermal data indicated that permafront was present. Index property, triaval compressive strength, consolidation and permeability data were obtained in the laboratory. Strengths ranged between 25 and 270 kPa for the fine material. Highly overconsolidated clays were encountered at the site farthest from shore. The preconsolidation pressure was estimated to be 15 MPa. Based on considerations of geologic and climatic history, it is proposed that the overconsolidation is a result of freezing and thawing

MP 1105 STRENGTH AND DEFORMATION OF FROZEN

Haynes, F.D., International Conference on Permariaynes, r.D., international Conference on Perma-frost, 3rd, Edmonton, Alberta, Canada, July 10-13, 1978. Proceedings. Vol.1, Ottawa, National Re-search Council of Canada, 1978, p.655-661, With Rus-sian and French summaries. 20 refs. 37-3760

FROZEN FINES, TENSILE STRENGTH, COM-PRESSIVE STRENGTH, FROZEN GROUND TEMPERATURE, DEFORMATION.

TEMPERATURE, DEFORMATION.
Results are given for tests made in uniaxial tension and uniaxial compression on frozen Fairbanks silt. These constant displacement rate tests were made over a strain rate range from .00016/s to 2.9/s and a temperature range from OC to 57C. Over these ranges athe compressive strength increased about one order of magnitude, while the tensite strength doubled over the strain rate range and increased about one order of magnitude over the temperature range. For increasing strain rate and decreasing temperature, the specific energy for the compression tests and the modulus increased, but the specific energy for the tension tests decreased. Expressions were developed for the strength as a function of strain rate and temperature. The increase in strength with higher strain rates and lower temperatures is explained by the strength of the see matrix, changes in the unifozen water content, and intergranular friction.

INFLUENCE OF FREEZING AND THAWING ON THE RESILIENT PROPERTIES OF A SILT SOIL BENEATH AN ASPHALT PAVEMENT.

Johnson, T.C., et al, International Conference on Per mafrost, 3rd, Edmonton, Alberta, Canada, July 10-13, 1978. Proceedings. Vol.1, Ottawa, National Research Council of Canada, 1978, p.662-668, With Rus-Cole, D.M., Chamberlain, E.J. 32-3761

PROZEN FINES, FREEZE THAW CYCLES, ROADS, PAVEMENTS, STRESS STRAIN DIAGRAMS, MODELS.

GRAMS, MODELS.

Stress-deformation data for silt subgrade soil were obtained from in-situ tests and laboratory tests, for use in mechanistic models for design of pavements affected by frost action. Plate-bearing tests were run on bituminous concrete pavements constructed directly on a silt subgrade, applying repeated loads to the pavement surface while the silt was frozen, thawing, thawed, and fully recovered. Repeated-load laboratory trainal tests were performed on the silt in the same conditions. Analysis of deflection data from the is-situ tests showed resiliant moduli of the silt as low as 2000 kPa for the critical thawing period, and 100,000 kPa or higher when fully recovered. Analysis of the laboratory tests, which gave moduli comparable to the latter values, showed that resilient modulus during recovery from the thaw-weakened condition can be modeled as a function. Sechanging mossture content. changing moisture content.

Linell, K.A., et al, International Conference on Permafrost, 3rd, Edmonton, Alberta, Canada, July 10-13, 1978. Proceedings. Vol.1, Ottawa, National Research Council of Canada, 1978, p.813-819, With Russian and French summaries. 9 refs.

Lobacz, E.F. 12-1781

TUNNELS, PERMAFROST CONTROL, COOL-ING SYSTEMS

Tunnels and shafts in permafrost encounter special portal problems because of instability of surface materials during than, tendency for see formation within the tunnel from annual than zone scepage, and necessity for control of air temperatures within the tunnel during summer. In constructing a tunnel in permafrost at Fox, Alaska, these problems were successfully solved. The unstable ground slope at the tunnel entrance was stabilized by use of a blanket of clean natural gravel. Refrigerant pipes imbedded in the backfull above the portals were used with a mechanical refrigeration system to insure a frozen zone around the tunnel where seepage would otherwise enter in summer. An insulated builkhead containing doors permitted exclusion of warm summer air. Entrance to a vertical shaft connecting to the rear of the tunnel was kept shaded in order to minimize seepage entrance in summer. Tunnels and shafts in permafrost encounter special portal seepage entrance in summer

MP 1108 CONSTRUCTION ON PERMAFROST AT LONG-

Tobiasson, W. International Conference on Perma-frost, 3rd, Edmonton, Alberta, Canada, July 10-13, 1978 Proceedings, Vol.1, Ottawa, National Re-search Council of Canada, 1978, p.884-890, With Russian and French summaties. 6 refs. 17, 1701

ROADS, FLOOD CONTROL, BUILDINGS, PER-MAFROST BENEATH ROADS, FOUNDATIONS, PAD FOUNDATIONS, PERMAFROST DEGRA-

Facilities at Longycarbyen were designed and are being operated with an appreciation for the importance of preserving permafrost. Portions of the network of gravel roads and paved runway were constructed on ice-rich permafrost. Ditches, culverts and bridges have been need to accommodate large peak flows since flash floods have occurred. Some difficulties have been experienced with progressive degradation large peak flows since flash floods have occurred. Some defficulties have been experienced with progressive degradation of permafrost by surface and groundwater. Damming a low area and pumping out brackish water has created a year-round water supply lake. The post and post foundation concept used extensively has proved quite successful. The hangar is an impressive use of an elevated floor above permafrost. Older buildings have been stabilized by adding slag insulation above supporting soils and installing open skirting below the first flowr. Water lines and other utilities are supported on timber bents anchored in permafrost.

MP 1109 DETAILS BEHIND A TYPICAL ALASKAN PILE FOUNDATION.

BUILDINGS. FOUNDATIONS, PERMAFROST BENEATH STRUCTURES.

When a sprehouse at Barter Islama burness used to the new foundation consists of forty-five steel pipe pulse, 25 m in dismeter, set in 4.6 to 5.8 m deep holes made with a 46 m dismeter sugger. The annotes was backfilled with a sand-water slurry. Starty manifested using thermocouples. As When a worehouse at Barter Island burned down, a replacement The samelus was backfilled with a sand-water slurry. Starry freezeback was closely monitored using thermocouples. As freezeback was rapid, the contractor was allowed to set steel beams on a pile five days after it was installed and post concrete ten days after the last pile was set. Groundwater problems during July required casing of suggered holes with 51 m diameter pipe to a depth of 1 m. Mechanol difficulties and lack of a crane slowed pile installation, but contractor resourcefulness got the job done clevation surveys and thermocouple measurements indicate that the foundation is solidly frozen and stable.

MP 1110 LAND APPLICATION OF WASTEWATER IN PERMAFROST AREAS.

Sletten, R.S., International Conference on Permafrost, 3rd, Edmonton, Alberta, Canada, July 10-13, 1978. Proceedings. Vol.1, Ottawa, National Research Council of Canada, 1978, p.911-917. With Russian and French summaries. 14 refs.

WASTES, WASTE TREATMENT, WATER TREATMENT, IRRIGATION.

TREATMENT, IRRIGATION.

Land application of wastewater can serve as a high performance treatment system, as a final disposal step for treated efficients, and as a polishing step for partially treated efficients. Experimental studies conducted near Farthanks, Alaska, during 1974-76 meetings both high (5.5 to 152 meters/year) and low rate (0.6 to 5.5 m/yr) systems for the purpose of polishing aerated lagoon efficient to meet secondary treatment enterns. Results from the slow rate system indicate that drusking water quality can be achieved. However, even though nitrogen remoral is not as great, the high rate (rapid infiltration) system is considered to be more feasible for cold climate conditions became the need for winter storage is less, the system does not rely on vegetative uptake, and the free-draining, consistential solis necessary for such systems can be found in alluvial valleys and coastal areas where many Arctic communities are located. For most wastewater constituents, high rate systems are capable of sustained, effective performance in extreme climates.

MP 1111 RADAR ANISOTROPY OF SEA ICE DUE TO PREFERRED AZIMUTHAL ORIENTATION OF THE HORIZONTAL C-AXES OF ICE CRYS-

ICE CRYSTAL STRUCTURE, SEA ICE, OCEAN CURRENTS, RADAR ECHOES, ANISOTROPY.

CURRENTS, RADAR ECHOES, ANISOTROPY. Results of impedie radar, see crystal casis and sub-see current measurements on the fistisce near Narshal Island, Alaska, are presented. The crystal structure of the see was found to have a horprontal crystal casis with a preferred arimithal corentation. This orientation was found to algar with the direction of the current at the see water interface. Impulse radar reflection measurements revealed that the preferred orientation of the sea see crystal structure behaved as a microwave-polariter. It was observed that when the antenna E-field was oriented parallel with the c-axis of the crystal platelets a strong reflection of the radar signal from the bottom of the see was obtained. However, when the antenna E-field was oriented perpendicular to the c-axis, no bottom reflection was detected. The results of this study fully support earlier reports of sea see in-homogeneity and anisotropy in reference to both structure and electromagnetic energy transmission.

PRELIMINARY ANALYSIS OF WATER EQUIVALENT/SNOW CHARACTERISTICS USING LANDSAT DIGITAL PROCESSING TECHNIQUES.

Merry, C.J., et al, Eastern Snow Conference, Feb. 3-4, 1977, Beileville, Ontario, Canada. Proceedings. 1977, 16 leaves, 20 refs. McKim, H.L., Cooper, S., Ungar, S.G.

REMOTE SENSING, DATA PROCESSING, SNOW WATER EQUIVALENT, SNOW DEPTH. SNOW WATER EQUIVALENT, SNOW DEPTH. The primary emphases of this analysis were to evaluate the accuracy of mapping the accal extent of snow and to determine the relationship between the water equivalent of the snowpack and the radiance obtained from the LANDSAT digital data. The test area selected for this task was the Dickey-Lincoln School Lakes Project located above the confluence of the St. John and Allagash Rivers in northern Maine. The computer alsorithm utilized in this study uses two features—"color" and "albedo" of the LANDSAT digital data to classify the multispectral data into land and water categories. Three snow commes (Allagash B. Beech Ridge and Ninemine B) yielding snow depth and water equivalent data were located. This task was accomplished using computer-guerated gray scale printouss (scale I 24,000) and topographic maps. The preliminary results indicated that the snow radiance values females of 9.5 inches. Extrapolation of these radiance values for the entire watershed can be used to map the arcal extent of snow contrivegration with a water equivalent value of 9.5 inches which enables computation of potential water runoff.

USE OF THE LANDSAT DATA COLLECTION SYSTEM AND IMAGERY IN RESERVOIR MANAGEMENT AND OPERATION.

Cooper, S., et al, Waltham, Massachusetts, U.S. Army Corps of Engineers, 1977, c150p., Numerous refs. Buckelew, T.D., McKim, H.L., Merry, C.J. 32-3943

WATERSHEDS, REMOTE SENSING, SPACE-BORNE PHOTOGRAPHY, COMPUTER AP-PLICATIONS, SNOW WATER EQUIVALENT.

PLICATIONS, SNOW WATER EQUIVALENT.

The New England Division Coops of Engineers demonstrated the use of the data collection and imagery systems in watershed and interfaced with a computer to provide an amounting proud receiver station which operated nearly continuously for over 18 months. Adequate reliability for operational use was goosen, and daily procedures were conjected to one half hour of operation time per day. Comparisons of costs and operation constraints were drawn among Landson DCS, GOES DCS, and groud based radio. Comparer own pathle tapes of Landson imagery were analyzed to evaluate the marging accuracy of the area of shown to determine a relationship between the water equivalent of a stowpack and the radiance recorded in Landson digital data, and to defining writinals and flood areas in New England. Sense interfaces were developed and evaluated for the collection of real time environmental data was the Landson DCS.

In support of the Advanced Research Projects Agency (ARPA) Arctic Surface Effects Vehicle (ASEV) Program, traffic tests were conducted during the summer of 1971 near Barrow, Alaska, on various types of tundra terrains using an SK-5 Air Cushion Vehicle. The main objectives of the study were to investigate the effects of air cushion vehicle operations and traffic on tundra, specifically, the extent and pattern of erosion, the degree of damage, initial and permanent, to the vegetation, the subsequent effect on the soil thermal regime due to any surface disturbance by the ACV, and to compare the general ecological impact of ACV traffic with that of other ground vehicles

MP 1124 DIFFICULTIES OF MEASURING THE WATER SATURATION AND POROSITY OF SNOW. Colbeck, S.C., 1978, 20(82), p.189-201, 26 refs.

WET SNOW, SNOW WATER CONTENT, POROSITY, SATURATION, MEASURING INSTRUMENTS, ACCURACY, REMOTE SENSING. STRUMENTS, ACCURACY, REMOTE SENSING.
Liquid saturation and porosity control most of the important material properties of wet snow, hence accurate measurements of these two parameters are of the utmost importance for both field research and glaciological applications. Nevertheless, most of the instruments in use are not capable of making accurate determinations of saturation. An error analysis shows that only direct measurements of the liquid volume can provide accurate values of water saturation, hence the melting calorimeter is inherently inaccurate While centrifuges extract some of the liquid for direct measurement, there is always some residual liquid left, depending on the grain size and structural parameters of the ice matrix. Therefore, some uncertainty exists over the interpretation of the data obtained from centralizer. grain size and structural parameters of the ice matrix. Therefore, some uncertainty exists over the interpretation of the data obtained from centrifuges. High-frequency capacitance probes can be used either in situ or on the surface and are very sensitive to the volume of hquid present. Capacitance probes are by far the best of the available devices

1977 TUNDRA FIRE IN THE KOKOLIK RIVER AREA OF ALASKA.

The focus of this paper is on the results of laboratory tests on polycrystalline, isotropic snow ice. Test temperatures ranged from OC to -56C, and strain rates ranged from O01/sec to 0 1/sec. Tests in both uniaxial compression and uniaxial tension were made on dumbbell shaped specimens

MP 1128 ICEBERG THICKNESS AND CRACK DETEC-TION.

Kovacs, A., International Conference and Workshops on Iceberg Utilization for Fresh Water Production, Weather Modification, and Other Applications, 1st, lowa State University, Ames, October 2-6, 1977. Proceedings. Edited by A.A. Husseiny, New York, Pergamon Press, 1978, p.131-145, 18 refs.

ICEBERGS, ICE COVER THICKNESS, RADAR ECHOES, ICE ISLANDS, CREVASSES, ICE CRACKS, ANTARCTICA—MCMURDO SOUND. CRACKS, ANTARCTICA—MCMURDO SOUND. Results obtained with an impulse radar system used to profile the thickness of and detect cracks in a tabular iceberg in McMurdo Sound, Antarctica, and an nee island in the Beaufort Sea near Flaxman Island, Alaska, are presented. Graphic records are shown of the radar impulse travel time which clearly reveal, for the first time, the bottom relief of each cice formation. Also detected in the antarctic iceberg was an echo signature from an infiltration-brine layer. The impulse radar signature of a 3-m wide creviase in the McMurdo Ice Shelf is also shown. The time of flight of the radar impulse in the ice island is compared with a 24.05-m drill hole measurement of the ice thickness. The effective velocity of the radar impulse in the ice island was found hole measurement of the ice thickness. The effective velocity of the radar impulse in the ice island was found to be 0.16m/ns and the effective dielectric constant of the ice to be 3.5. The findings show that tabular icebergs are flawed by cracks or crevasses which could be expected to propagate through the ice when an iceberg reaches the edge of the pack where it is subject to stresses induced by sea swell and waves (Auth.)

MATHEMATICAL MODELS, SOIL WATER MI-GRATION, HEAT TRANSFER, FROST HEAVE, FROST PENETRATION.

A mathematical model of coupled heat and moisture flow in gols has been developed. The model includes algorithms A mathematical model of coupled heat and moisture flow in soils has been developed. The model includes algorithms for phase change of soil moisture and frost heave, and several types of boundary and initial conditions are permitted. The finite element method of weighted residuals (Galerkin procedure) was chosen to simulate the spatial regime and the Crank-Nicolson method was used for the time domain portion of the model. Comparison of simulated and experimental data illustrates the importance of unsaturated hydraulic conductivity. It is one parameter which is difficult to measure and for which only a few laboratory test results are available. Therefore, unsaturated hydraulic conductivities calculated in the computer model may be a significant source of error in calculations of frost heave.

MP 1132 SEA ICE PRESSURE RIDGES IN THE BEAU-FORT SEA.

Wright, BD, et al, 1AHR Symposium on Ice Problems, Luleå, Sweden, Aug 7-9, 1978 Proceedings, Part 1, International Association for Hydraulic Research, 1978, p.249-271, 10 refs.

Hnatiuk, J., Kovacs, A.

SEA ICE, PRESSURE RIDGES, ICE MODELS.

The ice cover in the Beaufort Sea is characterized by extreme irregularities in thickness which are produced by the motion irregularities in thickness which are produced by the motion and resulting deformation of the sea ice. Pressure ridges, which are an integral part of this irregular and formidable ice cover, are recognized as the largest and most hazardous tee formations. Here, a number of cross-sectional profiles of first and multi-year pressure ridges in the Beaufort Sea are presented, which include both free-floating and grounded ice forms. The cross-sections of these multi-year ridges suggest that they can be adequately described by one ridge model with a constant sait to keel ratio and geometry. It is shown that the ice comprising multi-year ridges is

solid, with the interblock voids existing at the time of their formation being completely filled with ice. Several first-year pressure ridge profiles are also discussed, which indicate that there ridges cannot be represented by any one geometric model as their sail to keel ratios and geometries are quite variable.

ICE COVER EFFECT, ICE NAVIGATION, SEDI-MENT TRANSPORT.

MENT TRANSPORT.

This paper examines the hydrodynamics of vessel passage through a restricted channel and the resulting potential for sediment translocation

Examples of field measurements are presented which show a complex pattern of changes in water current magnitude and direction. The constriction of the channel by a ship creates a drop in the water surface that travels with the ship. The application of the concepts of effective stress and upward seepage forces to the riverbed material predicts that the potential for sediment translocation increases upon the passage of this moving trough. Three modes of granular bottom sediment transport were observed: bed load, saltation, and a process referred to as explosive liquefaction. liquefaction.

MP 1134 ARCHING OF MODEL ICE FLOES AT BRIDGE PIERS.

Calkins, D.J., IAHR Symposium on Ice Problems, Luleå, Sweden, Aug. 7-9, 1978. Proceedings, Part 1, International Association for Hydraulic Research, 1978, p.495-507, 7 refs.

RIVER ICE, ICE FLOES, BRIDGES, PIERS, ICE PRESSURE, ICE MODELS, ICE DEFORMATION. PRESSURE, ICE MODELS, ICE DEFORMATION.

A model study of the formation of ice arching at the upstream faces of rounded bridge piers was conducted in a hydraulic flume Polyethylene plastic was used to simulate square ice floes of two sizes, 37 mm and 74 mm A power function relaining the upstream surface ice concentration to a size ratio (characteristic block size over pier span opening) distinguishes between the arching and non-arching conditions at velocities below the critical value for underturning of individual ice floes.

MP 1135 FRAZIL ICE FORMATION IN TURBULENT FLOW.

Muller, A., et al, IAHR Symposium on Ice Problems, Lulea, Sweden, Aug. 7-9, 1978 Proceedings, Part 2, International Association for Hydraulic Research, 1978, p.219-234, 9 refs. Calkins, D.J.

33.400

FRAZIL ICE, ICE FORMATION, TURBULENT FLOW, SUPERCOOLED WATER, ICE NUCLEI. FLOW, SUPERCOOLED WATER, ICE NUCLEI.

To study ice nucleation and heat transfer, frazil ice was produced experimentally under controlled conditions. Turbulence was generated by a moving grid in a turbulence jar, where water could be cooled below the freezing point. Frazil was observed by means of a schileren system and the number of ice particles was counted on photographs. No frazil ice formed, regardless of turbulence and foreign material, unless the water was seeded with ice nuclei. The number of particles grew during the experiment, the growth rate increased with greater supercooling and higher velocity of the grid. This indicates a multiplication process induced by secondary nucleation. The heat transfer per particle normalized with supercooling, and the size of the particles was constant in all experiments within the accuracy of measurement. From these observations, it can be concluded that the total ice production is predictable if the heat transfer per particle can be estimated from turbulence data and if the number of particles can be calculated. A nucleation theory is, however, not available and is regarded as the crucial question.

MP 1136 RIGHTING MOMENT IN A RECTANGULAR ICE BOOM TIMBER OR PONTOON.

Perham, R.E., IAHR Symposium on Ice Problems, Lulea, Sweden, Aug. 7-9, 1978 Proceedings, Part 2, International Association for Hydraulic Research, 1978, p.273-289, 5 refs.

ICE BOOMS, FLOATING STRUCTURES.

ICE BOOMS, FLOATING STRUCTURES.

The ability of an ice boom timber to restrain ice floes is governed by its capacity to float and to resist being overturned

Six mathematical equations that describe this capacity for a rectangular-shaped timber have been worked out and are prevented here. The limits of each equation are also given them dimensionless values of righting moment equations, and from them dimensionless values of righting moment may be calculated. The equations have been evaluated for some general conditions, and for a few specific cases involving water and wood, and for one case concerned with deugning a steel pontoon booin. The calculations were done by a computer program which is not included.

data provided include three graphs and two tables of dimension-less values. All in all, the information should be very useful in evaluating new designs of ice boom timbers and

ENTRAINMENT OF ICE FLOES INTO A SUB-MERGED OUTLET.

Stewart, D.M., et al, IAHR Symposium on Ice Problems, Luleå, Sweden, Aug. 7-9, 1978. Proceedings, Part 2, International Association for Hydraulic Research, 1978, p.291-299, 2 refs.

Ashton, G.D.

FLOATING ICE. WATER INTAKES, WATER

FLOW.

Results of a series of laboratory experiments in a flume to determine the conditions under which floating ice floes are entrained into a submerged outlet are reported. Entrainment is found to occur when a Froude number based on outlet velocity and submergence depth is exceeded and that critical Froude number is a function of the ratio of outlet height to upstream flow depth. The critical Froude number is also shown to asymptotically approach the Froude number corresponding to equilibrium accumulation thicknesses of ice floes at a surface obstruction as the outlet height approaches the flow depth. Interpretation and application to design of submerged outlets is discussed.

MP 1138 ICE ARCHING AND THE DRIFT OF PACK ICE THROUGH CHANNELS.

Sodhi, D.S., et al, IAHR Symposium on Ice Problems, Luleå, Sweden, Aug. 7-9, 1978. Proceedings, Part 2, International Association for Hydraulic Research, 1978, p.415-432, 25 refs.

Weeks, W.F.

SEAICE, DRIFT, WIND VELOCITY, CHANNELS (WATERWAYS), ICE MODELS.

(WATERWAYS), ICE MODELS.

Models originally developed to describe the arching and the movement of granular materials through hoppers or chutes are applied to arching and drift of pack ice in straits and gulfs having lengths of 50 to 500 km. Verification of the usefulness of the models is attempted by making comparisons with ice deformation patterns as observed via satellite imagery in the Bering Strait region and in Amundsen Gulf The results are encouraging in that there is good correspondence between observed arching and lead patterns and those predicted by theory. In addition, values determined via the model for the angle of internal friction and the cohesive strength per unit thickness are similar to values obtained by other approaches It is estimated that if the wind velocity parallel to the Bering Strait exceeds 6 m/s, there will be ice flow through the strait. A one-dimensional formulation is presented, governing the ice pressure in a straight channel when the ice is stationary due to an ice arch or a boom.

EFFECT OF WASTE WATER REUSE IN COLD REGIONS ON LAND TREATMENT SYSTEMS. Iskandar, I.K., July-Sep. 1978, 7(3), p.361-368, 26 refs.

WATER TREATMENT, WASTE DISPOSAL, COLD WEATHER TESTS, SOIL CHEMISTRY.

COLD WEATHER TESTS, SOIL CHEMISTRY. The effect on ground water quality and soils and vegetation of treatment and disposal of municipal/industrial waste water on land in cold regions was investigated using six outdoor test cells. Winter application of waste water was feasible even at very cold air temperatures (<00C) at the New Hampshire test site High NO3-N concentrations were observed in all treatments (5-15cm/week) in both soils in early summer. This was explained as leaching of NH4-H stored over the winter months after its oxidation to NO3 in early spring. The principal mechanism for nitrogen removal was found to be plant uptake, which was seasonally dependent Application of 15 cm of secondary effluent per week to a sandy loam soil was not feasible because of the presence of >10mg/liter NO3-N in the leachate for >9 molyear Application of salts for road deceing during winter resulted in relatively higher concentrations of salts and Cl in the ground for a short period of time MP 1145

MP 1145 STATE OF KNOWLEDGE ON LAND TREAT-MENT OF WASTEWATER.

MEETINGS, WASTE TREATMENT, WATER TREATMENT, AGRICULTURE, FOREST LAND, MATHEMATICAL MODELS, LAND DEVELOP-

The objectives of this Symposium are to summarize the state of knowledge of the practical aspects of the treatment of wastewater by land application and to identify the suitable approaches for the design of such land treatment systems. The topics included are: site selection considerations, case studies of national and international concern, health effects of land treatment systems, pretreatment considerations, uses of wastewaters in agricultural and forest systems, monitoring, modeling and design criteria in two volumes. Volume 1 contains the invited papers presented and discussed at the conference Volume 2 contains shorter nanera about on-soine research that were contains the processory. The objectives of this Symposium are to summarize the contains shorter papers about on-going research that were selected from the responses received following a call for abstracts

USE OF REMOTE SENSING TECHNIQUES AND OTHER INFORMATION SOURCES IN REGIONAL SITE SELECTION OF POTENTIAL LAND TREATMENT AREAS.

Merry, C.J., International Symposium on the State of Knowledge in Land Treatment of Wastewater, Aug. 20-25, 1978, Hanover, New Hampshire. Proceedings, Vol.1, Hanover, U.S. Army Cold Regions Research and Engineering Laboratory, 1973, p 107-119, 27 cef.

SITE SURVEYS, WATER TREATMENT, WASTE TREATMENT, REMOTE SENSING, SPACE-BORNE PHOTOGRAPHY

Landsat, Skylab S190A Multispectral Photographic Camera, and Skylab S190B Earth Terrain Camera satellite data products, enlarged to scales of 1:500,000 and 1:250,000, were used to prepare land use maps for regional site selection of potential land treatment areas Interpretation of tonal and textural characteristics on the photography corresponded to vegetation, urban and agricultural land use categories. Color and color infrared transparencies augmented the land use mapping,

which was accomplished on black and white photographic prints. The three systems are compared in terms of areal coverage, resolution, and time of product preparation.

EVALUATION OF THE MOVING BOUNDARY THEORY IN DARCY'S FLOW THROUGH POR-OUS MEDIA.

Nakano, Y., International Symposium on the State of Knowledge in Land Treatment of Wastewater, Aug. 20-25, 1978, Hanover, New Hampshire. Proceedings, Vol.1, Hanover, U.S. Army Cold Regions Research and Engineering Laboratory, 1978, p.142-151, 22 refs.

BOUNDARY VALUE PROBLEMS, SOIL WATER MIGRATION, POROUS MATERIALS, ANALYSIS (MATHEMATICS), THEORIES.

YSIS (MATHEMATICS), THEORIES.
Traditionally in hydrology and soil physics, neither the water table nor the wetting front in Darcy's flow were believed to be singular surfaces. Recently, a new and conflicting theory has been advanced, using two different approaches. It has been shown, based upon continuum physics, that across both the water table and the wetting front local acceleration generally suffers a non-zero jump, and these two boundaries can be interpreted as acceleration waves This interpretation was found consistent with reported regularity results obtained from a purely mathematical viewpoint.

EVALUATION OF N MODELS FOR PREDICTION OF NO3-N IN PERCOLATE WATER IN LAND TREATMENT.

Iskandar, I.K., et al, International Symposium on the State of Knowledge in Land Treatment of Wastewater, Aug. 20-25, 1979, Hanover, New Hampshire. Proceedings, Vol.1, Hanover, U.S. Army Cold Regions Research and Engineering Laboratory, 1978, p.163-160, 61-61.

Selim, H.M. 33-653

WATER TREATMENT, SOIL CHEMISTRY, SEEPAGE, MATHEMATICAL MODELS.

SEEPAGE, MATHEMATICAL MODELS.

Nitrogen simulation models developed to describe one or more processes in agricultural soils can be adopted for land treatment. The most important processes in the simulation of N transformations for prediction of N in percolate water in land treatment are intrification, dentification, plant uptake and exchange of NH4 with the soil. The N model must be incorporated into a moisture flow model. It was concluded that the Michaelis-Menten type model is the most appropriate, although the first order kinetic may be used to describe the intrification process. Modeling the denirification process in slow infiltration must include biodegradable carbon and dissolved oxygen as limiting factors. Although several large models are available to simulate and predict N in leachate in land treatment, a need for a simplified model that can be tested in the field is apparent.

NITROGEN BEHAVIOR IN LAND TREAT-MENT OF WASTEWATER: A SIMPLIFIED MODEL

Selim, H.M., et al, International Symposium on the State of Knowledge in Land Treatment of Wastewater, Aug. 20-25, 1978, Hanover, New Hampshire Proceedings, Vol.1, Hanover, U.S. Army Cold Regions Research and Engineering Laboratory, 1978, p.171-179, 15 refs.

Iskandar, I.K. 33-654

WASTE TREATMENT, WATER TREATMENT, SOIL CHEMISTRY, SEEPAGE, MATHEMATICAL MODELS.

A simplified mathematical model was developed to describe A simplified mathematical model was developed to describe transformations and transport of nitrogen under transient soil water flow conditions. Kinetic reactions were assumed to govern the nitrification and denitrification processes. A macroscopic approach was used to incorporate plant uptake of water as well as NO3-N and NH4-N from the soil solution. The sensitivity of the model to changes in rate of N transformation, N uptake by plants, and schedule and amounts of N application were also investigated. The model can be used as a tool to predict the fate of nitrogen in land treatment systems. The model is flexible and can be adapted to incorporate various nitrogen transformation mechanisms as well as laverings in the soil profile mechanisms as well as layerings in the soil profile

OVERVIEW OF EXISTING LAND TREATMENT SYSTEMS.

WATER TREATMENT, WASTE TREATMENT, SOIL CHEMISTRY, COLD WEATHER PER-FORMANCE.

FORMANCE.

The objective of this study was to evaluate the performance of overland flow systems, especially during the winter months. Operation of the CRREL overland flow facility began in May 1977 and continued through the winter of 1977-78. The results of this study indicated that satisfactory BOD removal did not occur at soil temperatures below 4C

Based on this criterion, 105 days of storage would be needed at the CRREL site. This is 30 days less than the storage needs predicted by the EPA-1 computer program

GROWTH AND NUTRIENT UPTAKE OF FOR-AGE GRASSES WHEN RECEIVING VARIOUS APPLICATION RATES OF WASTEWATER.

Palazzo, A J, et al, Inter. Lional Symposium on the State of Knowledge in Land Treatment of Wastewater, Aug. 20-25, 1978, Hanover, New Hampshire Proceedings, Vol.2, Hanover, U.S. Army Cold Regions Research and Engineering Laboratory, 1978, p.157-162, 10-27. 163, 10 refs. McKim, H.L.

REPETITIVE LOADING TESTS ON MEM-

REPETITIVE LOADING TESTS ON MEMBRANE ENVELOPED ROAD SECTIONS DURING FREEZE-THAW CYCLES. Smith, N, et al, Oct 1978, 104(GT10), p.1277-1288, 15 refs. For other versions of this paper see 32-562 (MP 962) and/or 32-4407 (CR 78-12, ADA-056 744). Eaton, R.A., Stubstad, J. 33-645

FREEZE THAW TESTS, ROADS, SUBGRADE PREPARATION, PROTECTIVE COATINGS, DY-NAMIC LOADS

NAMIC LOADS.
Road test sections of impermeable membrane-enveloped silt and clay soils overlain with asphalt cement concrete were subjected to repetitive dynamic plate-bearing loadings to determine strength variations of the pavement systems during freeze-thaw cycles. The modulus values of the asphalt cement concrete vary inversely with its temperature by an order of magnitude in the temperature range of 110F to 30F. The resilient stiffness of the pavement system varied in the same manner by nearly a factor of eight. Despite the wide strength variations of the sections during freeze-thaw cycles, membrane can loped fine-grained soils can be utilized instead of granular materials as base and subbase layers in flexible pavements in cold regions where moisture migration is a major concern. Without the membrane protection such fine-grained soils that experience frost heaving migration is a major concern Without the membrane protection such fine-grained soils that experience frost heaving suffer severe bearing strength loss during thawing

PHYSICAL MEASUREMENTS OF RIVER ICE JAMS.

Calkins, D.J., Aug. 1978, 14(4), p.693-695, 5 refs. 33-641

RIVER ICE, ICE JAMS, MEASUREMENT, ICE COVER THICKNESS.

COVER THICKNESS.
River ace jam measurements have always been relatively difficult to obtain because of the uncertain stability of the floating ace mass. But recently two ace jams resolidified for about 3 weeks, allowing the ace thickness to be measured at several cross sections along their longitudinal profiles. The size distribution of surface are floes in one of the jams was also evaluated from low-level aerial photography. The ice jams were found to be thickness at the downstream end, of the order of 4-5 times the thickness of the ice cover before breakup, and decreased almost linearly in thickness upstream. The largest surface ice floes measured no none (c jam ranged from 0.27 to 0.05 of the river's average width (45m) The largest floes were at the downstream end, and floe size decreased progressively with distance upstream.

ICE MELTING, ARTIFICIAL MELTING, BUB-BLING, COMPUTERIZED SIMULATION
Results of laboratory experiments conducted to Jetermine bubbler-induced heat transfer coefficients are reported Implications and validity of results are discussed. As a second step, a procedure for computer-simulating the behavior of an ice sheet whose thickness is controlled by a bubbler system operating intermittently over a long period of time is developed. The simulation uses experimentally determined bubbler heat transfer coefficients, weather data, and a finite difference method to solve the equations governing the ice thickness and temperature profile. Through an example simulation, the usefulness of the procedure in predicting ice thickness and temperature profile. Through an example simulation, the usefulness of the procedure in predicting ice thickness and temperature profile. Through an example simulation, the usefulness of the procedure in predicting ice thickness and temperature profile histories, and the effectiveness or suitability of a given bubbler system are demonstrated.

MP 1161 DECAY PATTERNS OF LAND-FAST SEA ICE IN CANADA AND ALASKA.

Models, Sep. 6-9, 1977. Proceedings, Vol 2, Seattle, University of Washington, 1977, p.1-10, 11 refs. 33-1392

SEA ICE, FAST ICE, ICE COVER THICKNESS, ICE DETERIORATION, METEOROLOGICAL FACTORS.

FACTORS.

Weekly measurements of the thickness of land-fast sea ace made over a period of 10 to 15 years at a number of coastal locations in Canada and Alaska were analyzed. That portion of the data relating to maximum ice thickness and decay (i.e., the decrease in ice thickness) are presented and examined. Many meteorological and marine factors affect the decay process. This study investigates the effects of two important weather elements air temperature and solar radiation. Complete and reliable air temperature data for each station made it possible to analyze the relationship between accumulated thawing degree-days (ATDD) and sea ice ablation. The relationship between ice decrease and daily accumulated solar radiation was investigated, the results were comparable to those derived when ATDD was used were comparable to those derived when ATDD was used as the dependent variable. Other factors affecting ice ablation and breakup, such as snow-ice formation, snow cover depth, and wind, are also discussed in the study.

MP 1162 NEARSHORE ICE MOTION NEAR PRUDHOE BAY, ALASKA.

33-1394

SEA ICE, DRIFT, ICE TEMPERATURE, THER-MAL EXPANSION.

MAL EXPANSION.

Shorefast and nearshore pack ice motions in the vicinity of Prudhoc Bay, Alaska, have been monitored for the spring seasons (March-June) of 1976 and 1977. From the base camp on Narwhal Island, a barrier island 25 km northeast of Prudhoe Bay, a ranging laser was used to measure distances to targets located on the fast ice within a 7 km radius of the island. To assess packice motions, a radar transponder system with tracking stations located on Narwhal and Cross Islands was used to monitor the positions of transponders placed on the pack ice as far as 37 km northeast of the islands. These results suggest that gyre movement of slippage of the nearshore pack ice in this area apparently does not begin until early to mid-summer. The pack ice in this area responds slowly, and only weakly to local winds. The mesoscale displacements that occurred took place only after several days of consistent offshore winds

This indicates that a significant shoreward stress originating in the more distant pack heavily influences the dynamics of this nearshore area.

MP 1163 CHARACTERIZATION OF THE SURFACE ROUGHNESS AND FLOE GEOMETRY OF THE SEA ICE OVER THE CONTINENTAL SHELVES OF THE BEAUFORT AND CHUKCHI SEAS.

Tucker, W.B., Frank, M., Fungcharoen, S. 33-1395

SEA ICE DISTRIBUTION, SURFACE ROUGHNESS, SIDE LOOKING RADAR, PRESSURE NESS

RIDGES.

This paper reports on observations primarily made during the late winter and early spring of 1976 when the ice cover was at its maximum extent, and very few leads were observed. The primary sensors used were a laser profilometer and an X-band side-looking authorie radar (SLAR) system. The heaviest ridging was found at Barter Island and there was a general decrease in the number of ridges as one moved west into the Chukchi Sea. There was no strong variation in the mean ridge height along the coast. There was no systematic areal variation in mean ridge height normal to the coast. There was also no correlation between mean ridge height and the number of ndges per km as has been reported by previous investigators. An analysis was also made of the probability of encountering very large ridges SLAR imagery gives the size distribution of multiyear ice floes within the nearshore ice pack, and the variation in the areal percentage of deformed ice as a function of distance from the coast. This latter parameter showed a steady decrease as the distance north of the coast increases.

MODELING PACK ICE AS A VISCOUS-PLAS-TIC CONTINUUM: SOME PRELIMINARY RE-

SULTS.
Hibler, W.D., III, Symposium on Sea Ice Processes and Models, Sep. 6-9, 1977. Proceedings, Vol.2, Seattle, University of Washington, 1977, p.46-55, 21

PACK ICE, VISCOUS FLOW, PLASTIC FLOW, ICE DEFORMATION, ICE MODELS, MATH-EMATICAL MODELS.

EMATICAL MODELS.

A dynamic-thermodynamic model of pack ice is presented, which treats the ice as a nonlinear viscous continuum characterized by both bulk and shear viscosities and a pressure term with the viscosities being functions of the deformation rate and the pressure. The pressure is parameterized as a function of the compactness and mean thickness of the ice. This formulation allows the viscous continuum approach to be retained while allowing the system to deform in a plastic manner. The model is formulated in a fixed Eulerian and and the dynamical equations are counted to continuity. plastic manner The model is formulated in a fixed Eulerian grid, and the dynamical equations are coupled to continuity equations for compactness and mean ice thickness which include thermodynamic source and sink terms In the numerical scheme the dynamical equations of motion, in finite difference form, are integrated implicitly and the ice thickness equations are integrated explicitly. The model is applied to the Arctic Basin and integrated at one-day steps for up to eight years in order to obtain steady state results for both ice thickness and drift. Two cases are examined.

FINITE ELEMENT FORMULATION OF A SEA ICE DRIFT MODEL.

Sodhi, D.S., et al, Symposium on Sea Ice Processes and Models, Sep. 6-9, 1977. Proceedings, Vol 2, Seattle, University of Washington, 1977, p.67-76, 10 refs. Hibler, W.D., III.

33-1399

SEA ICE, DRIFT, MATHEMATICAL MODFLS

SEA ICE, DRIFT, MATHEMATICAL MODELS The complete boundary value problem of a linear viscous sea are drift model is presented, using the finite element method, and the formulation includes the inertial force term in the governing equation of motion. The results of the computations of the steady-state ice velocities in the Arctic Ocean are presented, using mean seasonal geostrophic wind data and available current information. The effect of varying handless conditions and the viscosity parameters is examined. data and available current information. The effect of varying boundary conditions and the viscosity parameters is examined On a much smaller scele, this model has been applied to the study of non-steady drift of pack ice through the Strait of Belle list (between Newfoundland and Labrador) where strong tidal streams and ocean currents move the pack ice back and forth. Using idealized sinusoidal variations of the tidal streams, it is found that the time lag between the water and the ice viscoties is related to the viscosity parameters, which indicates that the ice is not drifting freely, and the boundaries affect the time constant of the simplified first order model of the ice drift through the Strait first order model of the ice drift through the Strait

MP 1166 INVESTIGATION OF A VLF AIRBORNE RESIS-TIVITY SURVEY CONDUCTED IN NORTHERN MAINE.

Arcone, S.A., Dec. 1978, 43(7), p.1399-1417, 26 refs.

ELECTRICAL RESISTIVITY, AERIAL SURVEYS, VERY LOW FREQUENCIES, TOPOGRAPHIC EFFECTS, ELECTRIC FIELDS.

EFFECTS, ELECTRIC FIELDS.

Authorne wavetilt resistivity surveys and profiles at VLF have been analyzed for the effects of topography, altitude, and wavetilt phase and amplitude.

Topographic relief is known to affect at least one electric field component, flight altitude often varies over relief, and phase depends on the earth's resistivity stratification and the relative strength of displacement to conduction current.

A mountainous area in northern Maine of predominantly slate, but containing an igneous stock, was surveyed at 150 m mean flight altitude The 150-m survey was repeated at 300 m and two of the 150-m flight lines were repeated at a total of three other altitudes.

A comparison of the 150-m survey with the topography and with the 300-m survey revealed that although most of the resistivity information of the 150-m survey was retained at 300 m, serious differences arose due to topographic influences.

Profiles of the individual electric field components at the various altitudes then revealed that thopography was distorting resistivity values through its effect tield components at the various antitudes their revealed that topography was distorting resistivity values through its effect upon only the vertical component of the electric field. The separate influences of phase and amplitude were analyzed using the results of a ground survey of the total, complex surface impedance. The phase of the tilt proved to be important in the airborne differentiation of the rock types.

Merry, 0 33-1584

REMOTE SENSING, CONSTRUCTION MATERIALS, GEOLOGIC STRUCTURES.

MATERIALS, GEOLOGIC STRUCTURES.

Fourteen surficial geology units were delineated in a 2850 sq km area in northern Maine These units included alluvial fan, alluvial terrace, esker, floodplain, glacial moraine, kame, kame terrace, outwash, outwash terrace, bedrock, till, till over bedrock, wet outwash and wet till. The surficial geology units were field checked and then updated from the field reconsissance. The depths of the surficial geology units were estimated utilizing borchole data, field measurements and seismometer data. The areal extent of each surficial geology unit was quantified, using a planimetric color densitometer. The volumes of construction material were computed based upon these areal determinations and estimated depths. The volume estimates, compared with the estimates of required construction material, showed that more material could be found within the prescribed area around the dam and dike sites than was required for construction. It is believed that the east- and northeast-trending lineaments in this area are thrust faults dipping 45 deg to the northeast. The north-trending and N60W lineaments are probably strike-slip normal and reverse faults dipping 80 deg to nearly vertical faults should be negligible.

CREEP RUPTURE AT DEPTH IN A COLD ICE SHEET. Colbeck, S C., et al, Oct 26, 1978, 275(5682), p 733,

13 refs.

St. Lawrence, W.F., Gow, A.J. 33-1616

ICE SHEETS, ICE CREEP, FRACTURING, SEIS-MIC SURVEYS.

Experimental evidence has not supported the hypothesis that tectonic processes operating within glaciers and ice sheets are analogous to those in the Earth However, evidence of the existence of discrete shear planes within the antarctic ice sheet (31-1071 or F-17742) and evidence described here relating to the Greenland ice sheet indicate that faulting takes place at depth in cold ice sheets. The evidence suggests reconsideration of the concept of correspondence between flow and rupture at depth in the Earth and in cold ice sheets, as suggested earlier. Direct investigations at depth in ice sheets are made with relative case as compared to the nearly impossible task of direct measurements in the Earth's mantle. Experimental evidence has not supported the hypothesis that

EFFECT OF INUNDATION ON VEGETATION AT SELECTED NEW ENGLAND FLOOD CONTROL RESERVOIRS.

McKim, H.L., et al, Symposium on Remote Sensing for Vegetation Damage Assessment, Februar, 1978 Proceedings, 1978, 13p., 13 refs. Gatto, L.W., Merry, C.J., Cooper, S.

33-1519

REMOTE SENSING. INFRARED PHOTOGRA-PHY, VEGETATION PATTERNS, DAMAGE, FLOODING.

The effect of inundation on vegetation caused by the regulation and impoundment of water at six New England flood control reservoirs during a June-July 1973 flood was assessed from color infrared photography and corroborative ground surveys. Percent of damaged trees was assessed on a pattern recognition and coloration basis. Correlative ground truth data showed that the deciduous trees, particularly silver maple and red oak, were least affected and that coniferous trees, especially white pine, were most affected by siltation and inundation Much of the understory vegetation, i.e., American and Eastern hop hornbeam, lost all leaves after inundation, but new buds and shoots appeared by late September 1973. A critical relationship, determined from ground transect profiles showing the relationship between species susceptibility and inundation time was that trees completely covered by flood waters for more than 90 hours showed the most apparent damage

TERWAYS), COST ANALYSIS.
This study addresses itself to the problem of removing brash ice from Frechette Point to Six-Mile Point of the Little Rapids Cut of the St. Marys River system and river system are described and estimates are made for partially clearing a channel 250 ft wide Rough costs, based on dollars per horsepower, indicate that it would cost between 1 and 2 million dollars per clear channel mile per year

MP 1171 DIELECTRIC PROPERTIES OF DISLOCA-TION-FREE ICE.

Itagakı, K., 1978, 21(85), p.207-217, In English with French and German summaries. 20 refs. 33-1867

ICE CRYSTALS, HOARFROST, DISLOCATIONS (MATERIALS), ICE ELECTRICAL PROPERTIES. Dielectric properties of dislocation-free hoar-frost ice crystals were measured in the audio-frequency range Anomalously small relaxation strength was found in the dislocation-free area of the crystal samples, while dislocations deliberately area of the crystal samples, while dislocations deliberately introduced by scratching the samples drastically modified the relaxation strength. Since measurements made in the area of high dislocation density indicated normal behavior, electrically charged dislocations are considered to be the source of the normally observed dielectric relaxation.

MP 1172 REGELATION AND THE DEFORMATION OF WET SNOW.

Colbeck, S.C., et al, 1978, 21(85), p.639-650, In English with French and German summaries 17 refs. Parssinen, N. 33-1901

WET SNOW, REGELATION, SNOW DEFORMA-TION, MODELS.

TION, MODELS.

The thermodynamics of phase equilibrium control the temperature distribution around the ice particles in wet snow. When the snow is stressed, pressure melting occurs at the interparticle contacts and the snow densifies. Densification is described by a physical model which simulates the heat flow, meltwater flow, and particle geometry. The effects of ionic impurities, liquid saturation, and particle size are demonstrated. Typical values of the temperature difference, inter-particle film size, and density are calculated as functions of time. The calculated rates of compaction are too large, hence, at some later time, the effects of simultaneous grain growth must be added to the model.

ICE LENSES, ICE FORMATION, SOIL WATER, SOIL FREEZING, HEAT TRANSFER, FROST HEAVE, ANALYSIS (MATHEMATICS).

HEAVE, ANALYSIS (MATHEMATICS).

A new concept of the freezing of water, called segregation freezing, is proposed to explain the creation of the suction force that draws pore water up to the interface of a growing ice lens. The temperature of segregation freezing is shown to be lower than that of normal freezing (in situ freezing). This difference determines the pressure that the ice lens exerts while growing and carrying the overlying weight. On the assumption that the soil structure is rigid, equations governing the simultaneous flow of heat and water are formulated and solved for the limit of time t to 0 with the combination of analytical and numerical methods. Numerical computation of the solution yields a result that is reasonable, compared with experience in laboratory and nature.

ISUA, GREENLAND: GLACIER FREEZING STUDY.

Ashton, G D., 1978, 74(174), p.256-264, 9 rcfs.

33-2086

GLACIER FLOW, CREEP, ICE REFRIGERA-TION, MINING, DRILLING, ANALYSIS (MATH-EMATICS), ICE TEMPERATURE.

A scheme for cooling the lower portion of the edge of the Greenland ice sheet, which abuts a potential mining operation is examined. At the mine site, the ore body is overlain with ice. Once the overburden is removed, however, the adjacent ice is expected to flow toward the pit. One possible means of slowing this movement is to cool the ice below its present temperature to achieve a reduction in the creep rate and a retardiation of basal silp. The present study examines analytically the magnitude of cooling which may be accomplished by glilling a series of vertical holes about the periphery of the mine site. Refrigeration is accomplished by pumping a coolant downhole in a central pipe, then uphole in an annulus between the pipe and hole wall, and then through a thin walled pipe exposed to the cold surface climate above the ice sheet. Results of example calculations for various particular combinations of the free parameters are examined and include cooling requirements, hold spacing, pump requirements, and other parameters. Over a period of operation on the order of a year of more, it appears possible to cool a substantial part of the lower area of the glacier on the order of 1 to -2C, using a hole spacing that is considered reasonable. The results of the study are to be used as input to a detailed glacier flow study.

LINES.
Field soundings using an impulse radar system were carried out during May 1976 along a section of the Alyeska Pipeline near Pump Station 3 and the pump station feeder gas pipeline trench near the Happy Valley Camp, Alaska. The radar system, operating on the ground, provided a continuous profile of the near-surface geological structure of the permarfost. A unique dual antenna configuration produced two profiles, a vertical profile and an offset profile, from which the velocity of the radar signal at any point along the traverse could be calculated and from which a representative depth scale for the subsurface profile was determined. The profile results proved useful in identifying regions of massive ce in the permarfost. Logs from holes dililed for the oil pipeline's Vertical Support Members are compared with the radar profile data. This compansion shows that the radar detected the top and bottom of massive ice to a reader detected the top and bottom of massive ice to a depth of approximately 30 ft.

RESILIENT RESPONSE OF TWO FROZEN AND THAWED SOILS.

Chamberlain, E.J., et al, Feb. 1979, 5(GT2), p.257-

271, 13 refs. Cole, D.M., Johnson, T.C.

SUBGRADE SOILS, SEASONAL FREEZE THAW, SOIL MECHANICS, STRESSES, LOW TEMPERA-

Values of resilient modulus and Poisson's ratio were determined for silt and clay subgrade materials subjected to seasonal freezing and thawing. A new technique employing noncontacting variable impendance transducers was employed to obtain radial strain data for calculation of Poisson's ratio. The data were analyzed using multiple linear regression and analysis of variance techniques to obtain empirical relationships between the resilient moduli and Poisson's ratio parameters and stress and material property variables Resilient modulus data ranged from over 6,000,000 psi for the frozen condition to less than 600 psi for the thawed condition. Poisson's ratio ranged from 0.07 to 0.61, the majority of the values falling between 0.03 and 0.50.

GLACIER ICE, ICE STRUCTURE, OXYGEN ISO-TOPES, THERMODYNAMIC PROPERTIES.

An analysis of the oxygen isotope content of ice of the englacial and basal zones of the Matanuska Glacier at its terminus reveals the origin of the ice and entrained debris. The decrease with depth in the change of Ol8 values of ice of the diffused facies of the englacial zone and the dispersed facies of the basal zone is consistent with previous studies and indicates this ice originates in the accumulation area. Characteristics of the ice and debris of the dispersed facies indicate a subglacial source for most of the debris. The sharp increase of more than 4 per mill in the change

of O18 values of ice of the lower, stratified facies of the basal zone and its young radiocarbon age indicate this facies formed by subglacial freezing of isotopically enriched meltwater, probably surface-derived, to the glacier sole. The bubble-poor, fine-grained ice, thickness, stratification, rounded pebbles, and undisturbed sedimentary structures in this facies support this conclusion. The location, extent, and rate of subglacial ice formation and sediment entrainment vary. The Matanuska Glacier is therefore thermally complex, with zones of ice at the glacier sole that are at or below the pressure-melting point.

PROJECTILE PENETRATION, PENETRATION TESTS, FROZEN GROUND, SNOW COVER.

TESTS, FROZEN GROUND, SNOW COVER.

In a winter environment, snow and frozen soil may be the most readily available materials for use in field fortifications. Design of effective fortifications requires detailed knowledge of the response of these materials to impact from projectiles and projectile fragments. Data for small arms projectile and simulated projectile fragment penetration into snow and frozen soil are presented. Results of penetration predictions made using both closed form and empirical solutions are compared with test results, and the prediction techniques themselves are discussed. Basic agreement between predicted and measured penetrations was obtained for the simulated projectile fragments, which tended to remain stable in the target materials. Penetration of 7.62 mm small arms projectiles into frozen soil targets is also predictable at velocities below about 600 m/s, above which they tend to become unstable and tumble in the target. In the case of the empirical solution, the results presented serve to extend its range of applicability to projectiles weighing less than 0.9 kg.

MAPS.

Crude oil was spilled on six of the major Prudhoe Bay plant communities at an intensity of 12 liters/sq m. The communities occurred along a topographic-monsture gradient. The reaction of the major species of the various communities was recorded one year following the spills. Sedges and willows showed substantial recovery from crude oil spills. Mosses, lichens, and most dicotyledons showed little or no recovery. On a very wet plot with standing water, the vegetation showed very poor recovery. Dryss integrifolis M. Vahl, the most important vascular species on dry sites, was killed. Identical experiments using diesel oil rather than crude oil showed all species except an aquatic most obe killed. A sensitivity index for the communities was calculated on the basis of the percentage cover of the resistant species divided by the original total plant cover of the community. With this information an oil spill sensitivity map for an area of Prudhoe Bay was constructed for an accidental crude oil spill at nearby Franklin Bluffs. In this example all the community types are considered to have moderate to excellent recovery potential.

Prudhoe Bay crude oil and refined diesel fuel were applied to five topographically distinct tundra soils at Prudhoe Bay. Alaska. The penetration of hydrocarbons into the soil column depended on soil moisture and drainage characteristics. Biodegradation, shown by changes in the pristane to heptadecane and resolvable to total gas chromatographic area ratios, appeared to be greatly restricted in drier tundra soils during one year exposure. Some light hydrocarbons were recovered from soils one year after spillages Hydrocarbons were still present in soils at Fish Creek, Alaska, contaminated by refined oil spillages 28 years earlier, attesting to the persistence of hydrocarbons in North Slope soils. Prudhoe Bay crude oil and refined diesel fuel were applied

STUDY OF SEVERAL PRESSURE RIDGES AND ICE ISLANDS IN THE CANADIAN BEAUFORT

PRESSURE RIDGES, ICE ISLANDS, ICE COVER THICKNESS, PROFILES.

THICKNESS, PROFILES.

The environmental conditions in the southern Beaufort Sea are described, with special emphasis on pressure ridges and rec islands. Techniques for determining the geometric configurations and the physical and mechanical properties of sea-ice structures and ice islands are described. Profiles of pressure ridges were determined by surface surveys, drill-hole probes and side-looking sonar scanning. Multi-year pressure ridges with thicknesses up to 20 m and widths up to 120 m were examined in detail. The first-year ridge of 22 m thickness and 100 m width was studied. Results are given for several multi-year and the first-year ridges. Information obtained from dives under the ice and sea bed. A 20 m thick ice-island fragment grounded in 15 m of water was one of several investigated. Measurements of temperature, salimity, tensile strength, and compressive strength are given for ice taken from old pressure ridges, and factors influencing the interpretation of test data are discussed

ICE FOG, FOG DISPERSAL, CHEMICAL REAC-TIONS.

TIONS.

Ice fog suppression experiments on the Fort Wainwright Power Plant cooling pond were conducted during the winter of 1974-76 Hexadecanol was added to the pond and dramatically improved visibility by reducing fog generated from water vapor released by the pond at 1-4C Although this temperature was not low enough to create ice fog, the cold vapor fog created was equally as devastating to visibility in the vicinity of the pond During the winter of 1975-76, suppression tests were continued using films of hexadecanol, mixes of hexadecanol and octadecanol, and ethylene glycol monobutyl either (EGME) Suppression effectiveness at colder temperatures was studied and limits to the techniques were probed. A reinforcing grid was constructed that prevented breakup of the film by wind and water currents. Lifetime tests indicated that EGME degrades much more slowly than either hexadecanol or the hexadecanol-octadecanol mix. All the films were found to be very effective fog reducers at warmer temperatures but still allowed 20% to 40% of normal evaporation to occur. The vapor thus produced was sufficient to create some ice fog at lower temperatures, but this ice fog occurred less frequently and was more quickly dispersed than the thick fog that was present before application of the films

ICE COVER.

ice blockage of water intake structures can pose serious threats to the availability of cooling water at thermal power plants. Ice blockage difficulties are described as they may occur in invers, lakes, reservoirs, and estuaries, and as they may affect intakes either at the surface or submerged. Characteristics of both surface sheet ice and frazil ice are examined formational processes, sizes, thicknesses, movement or mobility, and modes of blockage or adhesion. Case histories of incidents of ice blockage of intakes are given. Solving ice blockage problems, either through original design, post-construction modification, or revised operational techniques is discussed.

EFFECT OF THE OCEANIC BOUNDARY LAYER ON THE MEAN DRIFT OF PACK ICE: APPLICATION OF A SIMPLE MODEL.

SFA ICE, PACK ICE, ALGAE, CRYOBIOLOGY, ICE BREAKUP, CHEMICAL COMPOSITION, WEDDELL SEA.

Analysis of data obtained during a 1977 cruise in the Weddell Sea indicates that the ice algal community found during that cruise is distinct from others that have been described that cruise is distinct from others that have been described (for example, the bottom epontic community in the land-sist ice in McMurdo Sound, the surface communities off 15:: Antarctica, and the bottom communities in Arctic Pack (acc) Unlike these other communities, the Weddell pack algae is dominantly n interior one, existing not at the surface or bottom but at mid-depth (65 to 215 m) within the ice. The form, ion of this community is dependent on the unique thermal and physical setting for Weddell sea pack ice. Brine drainage processes are initiated by summer warming, but are not carried through to completion as in the Arctic. This process causes a redistribution of salinity, maximizing in the mid-depth regions of the ice and apparently leading to algae production because of the ice and apparently leading to algae production because of the ice and apparently higher nutrient levels at these mid-depths. A qualitative model indicating the relationship between the thermally induced brine migration and subsequent algae growth is given.

FROZEN GROUND PHYSICS, UNFROZEN WATER CONTENT, NUCLEAR MAGNETIC RESONANCE, SOIL CHEMISTRY, SALINE

A simple, rapid method of determining the unfrozen water content of frozen soils is described in detail. The method content of frozen soils is described in detail. The method uses the first pulse amplitude of a pulsed nuclear magnetic resonance analyzer. Phase composition curves were obtained for four soils at very high total water contents. Three of the soils (Manchester fine sand, Fairbanks silt, and Goodrich clay) had been previously examined by another method (isothermal calorimeter). The fourth (Kotzebus silt) is a naturally saline soil found in low-lying coastal regions of Alaska. This soil was tested both in its natural state and with the soluble salts removed. The phase composition curves obtained by the nuclear magnetic resonance method are consistent with those obtained by using the isothermal calorimeter. tained by the nuclear magnetic resonance method are consistent with those obtained by using the isothermal calorimeter, but the nuclear magnetic resonance method saved time, requiring only 48h. It also provides a high degree of reproducibility and can be used over a wide range of temperatures. As expected, the unfrozen water content of the value soil was much higher in its natural state than after removal of the soluble salts. In addition, the unfrozen water content of all four soils appears to increase omewhat as the total water content of the sample is increased.

BUILDINGS. HEAT LOSS, TEMPERATURE MEASUREMENT, TESTS.

MEASUREMENT, TESTS.

A two-stage program for determining the applicability of various remote thermal scanning systems for detecting heat losses in buildings is desembed. The types of instruments tested are high resolution thermal imaging systems, low resolution thermal imaging systems, thermal line scanners and point radiometers. The first phase of this project consisted of inserting known building defects into a specially designed from at the USA Cold Regions Research and Engineering Laboratory and naving a representative of the manufacturer differences across the room envelope. The second phase of this project will consist of a field evaluation of these same instruments in approximately 10 cities, in cooperation with a weatherization program for low-income housing sponsored by the Community Services Administration and directed by the National Bureau of Standards. The goal of the second phase is to determine the cost effectiveness of various remote thermal scanning services. remote thermal scanning services

DETECTING WET ROOF INSULATIO WITH A HAND-HELD INFRARED CAMERA.

Korhonen, C., et al, Infrared Information Exchange,

Proceedings, St. Louis, Missouri, 978, p.A9-A15, 5 refs

Tobiasson, W. 33,3736

INFRARED PHOTOGRAPHY, ROOL, MOIS-TURE, DETECTION.

Since 1975, CRREL has used hand-held infra.ed scanners for detecting wet insulation under built-up roof membranes.
Thermocouples installed on roofs have shown that temperature differences between areas of wet and dry insulation may exist during both the day and night. The optimum time to detect these differences with an infrared camera is at night when solar interference is eliminated "urveys have night when solar interference is eliminated during based conducted successfully in many locations from Alabama to Alaska during both warm and cold weather. Three inch diameter core samples of the roof membrane and insulation have been obtained to verify infrared finding. This paper briefly overviews the technique used to survey roofs for moisture and then prevents results of a controlled experiment at Pease AFB, New Hampshire, to show the correlation between thermal images and temperature differences observed thermoelectrically in wet and dry portions of a roof. Measurem its of the thermal resistance of the wet and dry are commisted the physical picture. complete the physical picture

REMOTE DETECTION OF WATER UNDER ICE-COVERED LAKES ON THE DETH SLOPE

MAPPING.

The objectives of the work described in this report were to use and evaluate new radiowave methods of measuring earth resistivity in the LF and VLI bands and to develop estimated effective ground resistivity maps in this same band for the United States, including Alaska. Both airborne and ground methods were investigated by using the wascill and surface impedance techniques. It is concluded from the VLF study that over much of the central United States VLF airborne resistivity might well approximate LF ground methods discussion concerns the surface impedance method in the LF band. It is concluded from the LF studies that the present conductivity map is fairly accurate for BCB purposes but inapplicable to LF-purposes.

ICE PILE-UP AND RIDE-UP IN ARCTIC AND SUBARCTIC BEACHES.

Kovacs, A., et al, Internations' onference on Port 22 refs.

Sodhi, D.S. 33-4610

SEA ICE, SHORES, PRESSU E RIDGES, ICE PUSH

PUSH.
Information on shore ice pile-up and ride-up in arctic and subarctic waters is pr. 2d. Cross-sectional profiles of several ice pile-ups and inde-ups are presented, from which models and theoretical analyses were made. The expressions derived pive the force required to overcome gravitational potential and friction occurring during ice-piling and ride-up. It was estimated that the distribut 5 force required during ice-piling or ride-up was of the order of 10 to 350 kPa (about 15 to 50 psi). Field obstructions revealed that shore i.e. p.i-cup or ride-up appears to recur within a period of less than 30 minutes at any time of year, but most often in the spring and fall. Pile-up seldom occurs more than 10 m inland from the s., but ride-up frequently extends 50 m or more inland, regardless of ice thickness. While steeply sloping shores do not favor ice ride-up, sea ice has mounted the steep, 9-m-high bluff at Batrow. Alaska, destroying structures and taking lives.

TEMPERATURE EFFECT ON THE UNIAXIAL STRENGTH OF ICE.

Hayne F.D, International Conference on Port and Ocean ineering Under Arctic Conditions, 5th, Trondn. ..., Norway, Aug. 13-18, 1979. Proceedings, Vo. 1, Trondheim, University, 1979, p 667-681,

33-4632

ICE STRENGTH, COMPRESSIVE STRENGTH, TENSILE PROPERTIES.

TENSILE PROPERTIES.

The effect of temperature on the uniaxial strength of fine-grained, polycrystalline ice was investigated Dumbbell-shaped specimens were loaded in uniaxial compress on and uniaxial tension. Two machine speeds, 0.847 mm/s and 84.7 mm/s, were used for the tests, and the test temperatures ranged from -0.1 to -54C. The uniaxial compressive strength is very sensitive to temperature, generally increasing as the temperature decreased from -0.1C to -54C. The tensile strength is not very sensitive to temperature, but did continue to increase with decreasing temperature. Tensile strength also increased the most between -0.1C and -3C. An initial tangent modulus and a 5° stress modulus were found for each compression test. The initial tangent modulus increased about two times as the temperature decreased from -0.1C to -54C. The 50° stress modulus also increased with decreasing temperature. A secant modulus was found for the tensile tests and it tended to decrease with decreasing temperature. The specific energy required to cause failure was also found for the tensile tests and it tended to decrease with decreasing temperature. temperature. The specific energy required to cause failure was also found for the compression and tension tests.

WET SNOW, SNOW COMPACTION, SNOW RE-MOVAL, SALINITY.

MOVAL SALINITY.

The compressibility of we' snow decreases with decreasing fund water content but increases with decreasing saminity. Also, the tendency for snow splashing on highways increases with decreasing salinity. These opposite effects are complicined by the fact that liquid water content and salinity are not necessarily incompandent. The amount of liquid present can be controlled somewhat by the road fading and salinity is generally determined by how much salt is applied to the road surface. For different situations in a property of the salinity of compaction of wet snow into ice. Here we provide a qualitative review of wet snow and suggest how an understrading of wet snow's behavior on a road surface might increase our ability to deal with snow removal problems.

LABORATORY TECHNIQUES, ICE ACCRETION, HELICOPTERS, ICE COVER THICKNESS, TEMPERATURE EFFECTS

TEMPERATURE EFFECTS

Experiments have been i.e. ducted to provide a basis for a computer model that simulates atmospheric ice accretion on a rotating blade. A comparison of the computer model simulation and experimental results reveals that general agreement exists within the temperature range 0 C to -25 C and the velocity range 0 to 60 m/s. Beyond 60 m/s the computer simulation over-predicts the thickness of the ice accretion at the leading edge. Below -25 C the simulation and experimental results disagree in that the simulation significantly overpredicts the thickness of the accretion at the leading edge.

SEA ICE, THERMODYNAMICS, HEAT TRANSFER, ICE COVER THICKNESS, MATHEMATI-CAL MODELS.

CAL MODELS.

A numerical model for the rimulation of sea ice circulation and thickness over a seasonal cycle is presented. This model is used to investigate the effects of ice dynamics on arctic ice thickness and air-sea heat flux characteristics by carrying out several numerical simulations over the entire Arctic Ocean featon is a second in the model is to couple the dynamics. In the chickness characteristics by allowing the ice interaction to become stronger as the ce-becomes thicker and/or contains a lower areal percentage of thin ice. The dynamics, in turn, causes high oceanic heat losses in regions of ice divergence and reduced heat losses in regions of convergence. To model these effects consistently, the ice is considered to interact in a plastic manner with the plastic, strength chosen to depend on the ice thickness and concentration. The thickness and concentration. The thickness and concentration with the plastic properties of the plastic manner with the plastic, strength chosen to depend on the ice thickness and concentration. The thickness and concentration in turn, evolve according to continuity equations which include changes in ice mass and percent of open water due to advection, ice deformation and thermodynamic effects.

STEADY IN-PLANE DEFORMATION OF NON-COAXIAL PLASTIC SOIL.

Takagı, S., 1979, Vol.17, p.1049-1072, 27 refs

34-860
SOIL CREEP, PLASTIC PROPERTIES, THEORIES, BOUNDARY VALUE PROBLEMS, ANALYSIS (MATHEMATICS).
Presented in this paper is the theory of the steady inplante deformation, obeying the Coulomb yield criterion, of
plastic soils whose strain rate and stress principal directions
are noncoasial. The constitutive equations including an

unknown noncoaxial angle are derived by use of the geometry of the Mohr circle and the theory of characteristic lines. A boundary value problem is solved by assigning to the non coaxial angle a set of such values that enable us to accommodate the presupposed type of flow satisfying the given be undary conditions in a given domain. The plastic material regulated by the Colomb yield enterion in implane deformation is, therefore, a singular material whose constitutive equations are not constant with material but are variable with flow conditions.

ANISOTROPIC PROPERTIES OF SEA ICE IN THE 50- TO 150-MHZ RANGE

Kovacs, A., et al, Sep. 20, 1979, 84(C9), p.5749-5759,

Morey, R.M. 34-963

SEA ICE, RADAR ECHOES, ICE CRYSTAL STRUCTURE, OCEAN CURRENTS, DIELECTRIC PROPERTIES, ANISOTROPY.

TRIC PROPERTIES, ANISOTROPY.
Results of impulse radar studies of sea ice near Prudhoe Ray, Alaska, show that where there is a preferred current direction under the ice cover, the crystal structure of the ice becomes highly ordered. This includes a crystal structure with a preferred horizontal c axis that is onented parallel with the local current. The radar studies show that this structure behaves as an anisotropic dielectric. The result is that when electromagnetic energy is radiated from a dipole antenna in which the E field is onented perpendicular to the c axis azimuth, no bottom reflection is detected. It was also found that the frequency dispersion of anisotropic sea ice varies in the horizontal plane. This is demonstrated by the center frequency of the reflected signal spectrum, which is maximum in the preferred c axis direction and minimum perpendicular to it. In addition, it was found that the frequency dispersion is related to the average bulk brine volume of the ice but that the bulk dielectric constant of the ice, as determined from impulse travel time, shows little correlation with the coefficient of anisotropy.

ANALYSIS OF COUPLED HEAT AND MOISTURE FLOW IN AN UNSATURATED SOIL.
O'Neill, K., Jan. 1979, SR 79-36, Meeting on Model-

ing of Snow Cover Runoff, 26-28 September 1978, Hanover, New Hampshire. Proceedings, edited by S.C. Colbeck and M. Ray, p.364-309, ADA-167 767, 25 refs.

SOIL WATER MIGRATION, HEAT TRANSFER. This paper presents a set of partial differential equations that describes the concurrent one-dimensional flow of liquid and heat in unfrozen unsaturated soils. A Galerkin finite element method based on hermite polynomials was used to solve the equations numerically. To verify both the theory and the solution method, laboratory measurements were made on a horizontal soil column. The res. _s furnished essential transport coefficient values, as well as data records over space and time for infiltrations of cold water that produced steep, interacting temperature and moisture content gradients. Comparison of measured and predicted values showed very good agreement in both the moisture and temperature domains. Contrary to the usual assumption in soil studies, liquid convection played a large role in the heat transfer. A simple geometric mean formula represented the soil the small conductivity quite adequately. SOIL WATER MIGRATION, HEAT TRANSFER.

SURFACE-BASED SCATTEROMETER RE-SULTS OF ARCTIC SEA ICE.

NESS.
Radar zekscatter measurements were made of shorefast sea ice nes. Point Barrow, AK, in May 1977, with a surface-based FM-CW scatterometer that swept from 1-2 GHz and from 8.5-17.5 GHz. The 1-2 GHz measurements showed that thick tirst-year and multiyear ice cannot be distinguished at 10-70 deg ir idence angles, but that undeformed sea ice can be discriminated from pressure ridges and lake ice Results also indicate that frequencies between 8-18 GHz have the ability to discriminate between thick first-year, multiye-r, and lake ice Cross polarization was found to be a bet-r discriminator than like polarization I addition, at these latter frequencies the differential scattering was found to have an approximately linearly increasing frequency resp-1se. SNOW PHYSICS.

The grain boundaries in snow are generally unstable when the pote space is filled with liquid water (i.e., liquid-saturated snow). Thus, when unstressed snow is saturated with melt, the tice particles in snow are cohesionless spheres. This leads to very low strengths and to rapid grain growth due to heat flow among particles of different sizes. The grain boundaries in highly unsaturated snow (up to about 7% liquid by volume) with small applied loads are stable, and the grains must be arranged in clusters to achieve local force equilibrium. Two grains bond together with geometrical constraints on the radii of the phase boundaries. Three grains join at a liquid vein whose size is determined by grain size and capillary pressure (i.e., liquid "tension"). Sow grain growth occurs by sublimation, vapor diffusion, and condensation, and intergrain strength is relatively high. Once grain clusters are formed, equilibrium imposes constraints on the curvature of the phase boundaries which limit change in the capillary pressure

WATER TABLE, BOUNDARY VALUE PROB-LEMS, ANALYSIS (MATHEMATICS).

LEMS, ANALYSIS (MATHEMATICS).

The traditional viewpoint in hydrology and soil physics purports that water tables appearing in porous media described by Darcy's law and the extended Darcy's law are not singular surfaces. Several particular solutions in which singulanties occur are presented as counter-examples to the traditional viewpoint and as evidence supporting the new theory that water tables are generally singular surfaces.

WATER CHEMISTRY, GASES, VAPOR TRANSFER, POLLUTION, LABORATORIES.

FER, POLLUTION, LABORATOKIES.

The passage of mercury vapor from ambient air through the wa'b of conventional polyethylene (CPE), linear polyethylene (LPL), and Teflon (FEP) containers can seriously contaminate solutions of distilled and natural water stored in these containers. The rate of mercury contamination is dramatically increased when the sample solution contains oxidizing agents such as nitric acid or potassium permanganate, which are commonly used as preservatives to prevent loss of mercury (II) ion. The rate of contamination also depends on container material and decreases in the order CPE> LPE> FEP> see lass. Freezing the samples in plastic containers is an glass. Freezing the samples in plastic containers is an effective way to prevent mercury contamination. When freezing is not practical, storage in glass containination manufactures manufactures manufactures manufactures manufactures manufactures ample contamination from ambient mercury vapor.

CORRELATION AND QUANTIFICATION OF AIRBORNE SPECTROMETER DATA TO TUR-BIDITY MEASUREMENTS AT LAKE POWELL, UTAH.

Merry, C.J., International Symposium on Remote Sensing of Environment, 13th, Ann Arbor, Michigan, April 23-27, 1979. Proceedings, Environmental Research Institute of Michigan, 1979, p.1309-1316, 7 refs. 34 2043

VEYS, SPECTROSCOPY.

A water sampling program was accomplished at Lake Powell, Utah, duning June 1975 for correlation to multispectral data obtained with a 500-channel airborne spectroradiometer. Field measurements were taken of percentage of light transmittance, surface temperature, PH and Secchi dak depth. Percentage of light transmittance was also measured in the laboratory for the water samples Analyses of electron in crystephs and suspended sediment concentration data for four water samples located at Hite Bridge, Mile 168, Mile 168 Mile 150 and Bullfrog Bay indicated differences in the composition and concentration of the particulate matter. Authorne spectroradiometer multispectral data were analyzed for the four sampling locations. The results showed that: (a) as the percentage of light transmittance of the water samples decreased, the reflected radiance increased, and (b) as the suspended sediment concentration (rig/1) increased, the reflected radiance increased in the 1-50 mg/1 range. In concis on, valuable qualitative information was obtained on surface turbidity for the Lake Powell water spectra. Also, the reflected radiance measured at a wavelength of 0.58 micron was directly correlated to the suspended sediment concentration.

MP 1272 ON THE ORIGIN OF STRATIFIED DEBRIS IN ICE CORES FROM THE BOTTOM OF THE AN-TARCTIC ICE SHEET.

Gow, A.J., ct al, 1979, 23(89), p.185-192, In English with French and German summaries. 11 refs Epstein, S., Sheehy, W.

ICE CORES, DRILL CORE ANALYSIS, SEDI-MENTATION, STRATIFICATION, FREEZE THAW CYCLES.

THAW CYCLES.

Cores from the bottom 483 m of the antarctic ice sheet at Byrd Station contain abundant stratified debris ranging from alli-sized particles to cobbles. The nature and disposition of 'e debris, together with measurements of the physical properties of the inclosing ice, indicate that this zone of dirti-laden ice originated by "freezing-in" at the base of the ice sheet. The transition from air-rich glacial ice to ice practically devoid of air coincided precisely with the first appearance of debris in the ice at 483 m above the bed. Stable-isotope studies made in conjunction with gas-content measurements also confirm the idea of incorporation of basia ice may well constitute the most diagnostic test for discriminating between debris incorporated in a melti-refreeze process and debris entraped by purely mechanical means, e.g. shearing. We conclude from our observations en bottom cores from Byrd Station that "freezing-in" of

basal debris is the major mechanism by which sediment is incorporated into polar ice sheets. (Auth)

WATERSHEDS, DRAINAGE, STREAM FLOW.

WATERSHEDS, DRAINAGE, STREAM FLOW. A drainage network map of the Caribou-Poker Creek Research Watershed, near Fairbanks, Alaska, has been used to conduct a Strahler stream order analysis and an analysis of length distributions of source and tributary-source links in a subarctic watershed. The basins have very low drainage densities, ranging from 1.35 km/sq km to 5.34 km/sq km. Bifurcation ratios were higher than those found in watersheds in the continental U.S. Statistical analysis indicates that source and tributary-source links in a subarctic watershed belong to different length populations, the same as found in other regions of the world. Additional analysis indicates that exterior links originating on permafrost slopes tend to be shorter than those originating on non-permafrost (well-drained) slopes.

HIGH-FORCE TOWING.

Mellor, M., Feb. 1980, 1(3/4), p.231-240, 5 refs. 34-2445

ICEBERG TOWING, LOADS (FORCES)

ICEBERG TOWING, LOADS (FORCES).

Required force levels for iceberg towing at 1 knot could be at least 50 tons for protection of structures and drillships in northern waters, and around 1000 tons for iceberg exports from the Antarctic. Corresponding values of effective ("towrope") power are only 307 hp and 6140 hp, respectively. A conventional-hull supertrug capable of 1000 tons thrust would probably have T/P=10 lbf/hp, p=200,000 hp, and a propulsive efficiency of about 3%. The most practical expedient for antarctic towing seems to be use of multiple conventional tugs, with fewer tugs or higher speeds as the iceberg reduces its size and streamlines itself. The practical difficulty of towing antarctic icebergs may have been underestidifficulty of towing antarctic icebergs may have been underestimated, and it might be worth reconsidering preliminary shaping of the iceberg to reduce the drag. COMPARISON OF THE PEBBLE ORIENTA-TION IN ICE AND DEPOSITS OF THE MATA-NUSKA GLACIER, ALASKA.

awson, D.E., Nov. 1979, 87(6), p.629-645, 21 refs.

GLACIAL DEPOSITS, ICE STRUCTURE, SEDI-

MENT TRANSPORT. Depositional processes and their sediment source determine the orientation of pebbles in the deposits of the Matanuska Glacier and the relationship of this orientation to the direction of ice flow. Pebble fabrics in ice-derived deposits differ of ice flow. Pebble fabrics in ice-derived deposits differ from those in resedimented deposits: fabric in deposits from sediment flow, ablation of exposed basal zone ice, and the slumping and spalling of ice-cored slopes does not correspond to the ice flow direction, but is developed by these depositional processes. Pebbles in basal ice and melt-out till show a unimodal distribution of orientations, with individual observaà unimodal distribution of orientations, with individual observations only slightly dispersed about the mean axis. Pebble fabrics in other deposits are polymodal, with a significantly larger amount of dispersion about the mean axis. The regional pattern of mean axes of basal zone ice and meltiout till pebble fabrics approximates the local and regional trends of ice flow, but pebble imbreation in ice and sediment does not necessarily indicate the direction from which the glacier flowed. A small number of measurements of pebble orientations at many sites and the analysis of these data by the eigenvalue method appear to be suitable techniques for examining the pebble fabric of glacial deposits, but addition-

SEA ICE, ICE PHYSICS, ICE CRYSTAL STRUC-TURE, OCEAN CURRENTS.

Field observations at 60 sites located in the fast or near-fast ice along a 1200-km stretch of the north coast of

Alaska between the Bering Strait and Barter Island have shown that 95% of the ice samples exhibit striking c axis ments within the horizontal plane. In all cases the ne of preferred orientation increased with depth in the Representative standard deviations around a mean ice. Representative standard deviations around a mean direction in the horizontal plane are commonly less than 10 deg for samples collected near the bottom of the ice. The general patterns of the alignments support the correlation at the ice/water interface suggested by Weeks and Gow (1978) A comparison between c axis alignments and instantaneous current measurements made at 42 locations shows that the most frequent current direction coincides with mean c axis direction. The c axis alignments are believed to be the result of geometric selection, with the most favored orientation being that in which the current flows normal to the (0001) plates of ice that comprise the dendritic sea ice/seawater interface.

TRAVELING WAVE SOLUTIONS OF SATURAT-ED-UNSATURATED FLOW THROUGH POR-OUS MEDIA.

Nakano, Y., Feb. 16, 1980, 16(1), p.117-122, 9 refs.

WAVE PROPAGATION, WATER FLOW.

Traveling wave solutions to the problem of saturated-unsaturated flow of water through a uniform porous medium are derived, and the regularity properties of the solutions are studied. It is found that a singularity occurs in the higher-order derivatives of flux with respect to the space coordinate in the solutions at water tables and that the water tables be generally interpreted as propagating acceleration waves of the nth order, where n is a positive integer

PILOT SCALE STUDY OF OVERLAND FLOW LAND TREATMENT IN COLD CLIMATES.

WASTE TREATMENT, WATER CHEMISTRY, IRRIGATION, COLD WEATHER TESTS

IRRIGATION, COLD WEATHER TESTS.

Primary and secondary wastewaters were applied to separate sections of an overland flow site. The dimensions of each section were 3 m in width by 30 m in length and the system was graded to a five percent slope. The site was planted with orchard grass and tall fescue A one-year acclimation period was allowed to obtain a good cover. Wastewater was applied to the site for one month before onset of the study to establish a high level of microbial activity. Applied wastewater as well as surface and subsurface flows were monitored for NO-3, NH+4, TKN, BOD, suspended solids, Ph. conductivity and total phosphorius face flows were monitored for NO-3, NH+4, TKN, BOD, suspended solids, pH, conductivity, and total phosphorus The results indicate excellent warm weather performance for removal of oxygen demanding substances, suspended matter and nitrogen. Treatment efficiency of suspended solids remained high throughout the winter while treatment of BOD declined to unacceptable levels at soil temperatures below 4C. Nitrogen treatment declined rapidly below 14C. The form of nitrogen applied to overland flow was found to affect performance with nitrate being the less desirable form Phosphorus treatment by overland flow was found to be about 80% in the summer months, declining to nil during the winter.

RADIO COMMUNICATION.

Measurements of apparent resistivity and phase derived from the complex surface impedance of radio waves propagating in the ground wave mode at frequencies in the radio navigation, and and band (between 157 and 382 kHz) are presented Areas encompassing between 400 and 800 sq km that covered a vaniety of glacial sediments, land forms, and some crystalline bedrock types were surveyed. The degree of dispersion found in resistivity values reflects the dispersion in grain size, while the average resistivity increases with mean grain size. Dielectric properties are suggested as one cause of the low phases observed over crystalline bedrock. The combination of apparent resistivity and phase data implies that the resistivity measurements are consistent in about 50% of the areas with previous measurements of field strength attenuation performed in the AM broadcast band

MARGIN OF THE GREENLAND ICE SHEET AT

Colbeck, S.C., et al, 1979, 24(90), p.155-165, In English with French and German summaries. 7 refs AJ.

34-2824

ICE SHEETS, ICE EDGE, DRILL CORE ANAL-YSIS, ICE STRUCTURE.

Field studies at a particular place at the margin of the Greenland ice sheet have provided information about the ice sheet. Lee temperatures were measured in five drill holes, two of which reached the unfrozen area of basal

melting Surface water entered these two bore holes, reacting the base in one, but remaining 59 m above the base in the other. The existence of this water conduit or in the other. The existence of this water conduit or fracture at 240 m depth, the calculated temperature profiles, and the local bedrock configuration suggest an area of stationary ice overridden by the ice sheet. This situation suggests made above 240 m depth shows patterns similar to fabrics elsewhere near the margin in zones of low deviations stress. Unfortunately, no cores were obtained below that depth where stationary ice may exist.

Kohnen, H. 34-2823

ICE SHEETS, ICE MECHANICS, DRILL CORE ANALYSIS, RELAXATION (MECHANICS), ULTRASONIC TESTS. ANTARCTICA—BYRD STA-

TION.

Deep cores from Byrd Station were used to calibrate an ultrasonic technique of evaluating crystal anisotropy in the antarctic resishest. Velocities measured parallel and perpendicular to the vertical axis of the cores yielded data in excellent agreement with the observed e-axis fabric profile and with the in-situ P-wave velocity profile measured parallel to the bore-hole axis by Bentley Velocity differences in excess of 140 m/s for cores from below 1,300 m attest to the tight clustering of c axes of crystals about the vertical, especially in the zone 1,300-1,800 m. A small but significant decline in vertical velocity with ageing of the core, as deduced from Bentley's down-hole data, is attributed to the formation of oriented cracks that occur in the ice cores as they relax from environmental stresses. This investigation of cores from the 2,164 m thick ice sheet at Byrd Station establishes the ultrasonic technique as a viable method of monitoring relaxation characteristics of drilled cores and for determining the gross trends of c axis orientation in ice sheets. The retaxation characteristics of chiled cores and for determining the gross trends of c axis orientation in ice sheets. The Byrd Station data, in conjunction with Barkov's investigation of deep cores from Vostok, East Antarctica, also indicate that crystal anisotropy in the antarctic ice sheet is dominated by a clustering of c-axis about a vertical symmetry axis.

ANALYSIS OF CIRCULATION PATTERNS IN GRAYS HARBOR, WASHINGTON, USING REMOTE SENSING TECHNIQUES. Gatto, L.W., 1980, Vol.3, p 289-323, 45 refs. 34-2675

REMOTE SENSING, TIDAL CURRENTS. WATER FLOW.

WATER FLOW.

The objective of this investigation was to analyze surface circulation patterns in Grays Harbor, Washington, during flood and ebb tide, using National Aeronautics and Space Administration (NASA) aerial photographs and thermal-IR imagery and low altitude aerial photographs of uranine dye drogues. The application of LANDSAT-1 and passive microwave imagery was evaluated but did not prove useful. Water temperature, salinity, and suspended sediment data and the results of hydraulic model studies were used to venify and supplement interpretations from the photographs and imagery. The use of remote sensing techniques in conjunction with ground truth data and hydraulic model results, when available, provides a more complete perspective of estuarine processes than is available by using conventional shipboard surveys alone. shipboard surveys alone.

MP 1284 IMAGING RADAR OBSERVATIONS OF FROZ-EN ARCTIC LAKES.

Elachi, C., et al. 1976, 5(3), p 169-175, 14 refs. Bryan, M.L., Wecks, W.F.

RADAR ECHOES, FROZEN LAKES, BACK-SCATTERING, REMOTE SENSING, BUBBLES, ICE WATER INTERFACE, ICE SOLID INTER-FACE

L-band radar images of a number of ice-covered lakes located approx 48 km northwest of Bethel. Alaska, show large differences in radar backscatter with lakes showing homogeneous low-returns, homogeneous high-returns another low-returns around the lake borders and high-returns from the central areas. The patterns of the returns suggest that a low-return indicates that the lake is frozen completely to its bottom, while a high-return indicates the presence of freshwater between the ice cover and the lake bed. This interpretation is in good agreement with the limited information available on lake depths in the study area and recent X-band radar observations of North Slope lakes by Sellman, Weeks and Campbell, who suggested such an interpretation. These effects are, however, more striking in the L-band than in the X-band imagery. This can be explained by the fact that volume inhomogeneities, such as air bubbles, will cause more scattering and conductivity losses and thus more attenuation at the shorter wavelengths (X-band, 3 cm) I hand radar images of a number of rescovered lakes located

WATER MOVEMENT IN A LAND TREATMENT SYSTEM OF WASTEWATER BY OVERLAND FLOW.

Nakano, Y., et al, 1979, 11(4/5), p.185-206, 15 refs. Khalid, R.A., Patrick, W.H., Jr. 34-3949

WATER FLOW, WASTE TREATMENT, WATER TREATMENT, SOIL WATER, SATURATION, SEEPAGE, SLOPE ORIENTATION, EX-PERIMENTATION.

Water movement in an overland-flow land treatment system Water movement in an overland-flow land treatment system was studied experimentally and theoretically. A small-scale physical model was used to obtain experimental data. The theoretical analysis was based upon the shallow water equation for overland flow and the Darcy-Richards law for soil water flow. It was found that the water movement in the system was primarily controlled by the application rate, the friction slope, the slope angle, the hydraulic characteristics of soils, and the evapotranspiration. An approximate capabilities obtained to steady flow up the system was obtained to steady flow up the system was obtained. issues of soils, and the evapotranspiration. An approximate analytical solution to steady flow in the system was obtained it was found that the rate of soil water flow was mainly determined by the saturated conductivity of soils and in less extent by the friction slope and the slope angle in the steady condition. A finite difference solution to non-steady flow was found satisfactory in simulating the experimental data.

MP 1286 MASS-BALANCE ASPECTS OF WEDDELL SEA PACK-ICE.

Ackley, S.F., 1979, 24(90), p.391-405, In English with French and German summaries. 20 refs. 34-2840

SEA ICE DISTRIBUTION, MASS BALANCE, ICE DEFORMATION, SALINITY, WEDDELL SEA.

SEA ICE DISTRIBUTION, MASS BALANCE, ICE
DEFORMATION, SALINITY, WEDDELL SEA.

The Weddell Sea pack ice undergoes several unique advanceretreat characteristics related to the clockwise transport in
the Weddell Gyre, the physical setting for the pack ice,
and the free boundary with the oceans to the north. From
satellite-derived ice charts, the annual cycle of the pack
ice advance and retreat is depicted. The Weddell pack
advance is characterized by a strong cast-moving component
as well as the north advance seen in other regions such
as East Antarctica. Physical characteristics of the pack
ice at the summer minimum ice edge are presented. Indications are that deformation is a significant component of
the ice accumulation, deformed ice accounting for c 15
to 20% of the area covered in the year-round pack. Ablation
characteristics are inferred from observations made during
field work and from satellite imagery. These observations
indicate that surface-melt ablation typically seen on Arctic
pack is not seen on the Weddell pack inside the summer
edge. Using the physical-property data and transport inferred from ship and iceberg drifts, a new annual ice accumulation: > 3 m is inferred over the continental shelf in the
South compared to < 2 m previously estimated. The implication is that salt flux into the ocean over the shelf may
be significantly larger, thereby increasing the production of
Western Shelf Water. a component of Antarctic Bottom
Water. (Auth.) (Auth.)

DELINEATION AND ENGINEERING CHARAC TERISTICS OF PERMAFROST BENEATH THE BEAUFORT SEA.

ICE, ICEBERGS, AVALANCHES, SNOW, ICE.
This book reviews the dynamical aspects of snow and ice
masses on the geophysical scale. It is divided into seven
chapters, each of which describes the basic features of a
particular snow or ice mass. In each chapter a conceptual
framework is established on a physical basis, and a mathematical description is provided with as many references to the
technical literature as space allows. No attempt is made
to address particular applications of the information, but
the physical and mathematical descriptions of the properties
and processes provide for both an understanding of snow
and ice masses and a basis through which particular problems
can be addressed

ANALYSIS (MATHEMATICS).

Ice sheets are inhomogeneous; properties vary strongly with depth. Theoretical treatment of plates with properties varying perpendicular to the plate has now been satisfactonly developed for floating ice sheets. However, other problems are still waiting for solutions. The use of model ice is developing rapidly such ice are made. Some suggestions of how to analyze breakthrough-loads on ice sheets diminish with duration of loading, but no satisfactory solution is available based upon classical procedures of applied mechanics.

EXPERIENCE GAINED BY USE OF EXTEN-SIVE ICE LABORATORY FACILITIES IN SOLV-ING ICE PROBLEMS.

Frankenstein, G.E., Symposium on Physics and Mechanics of Ice, Copenhagen, Aug. 6-10, 1979. Proceedings. Edited by P. Tryde, Berlin, Springer-Verlag, 1980, p.93-103, 12 refs.

ICE MECHANICS, ICE NAVIGATION, ICE CON-DITIONS, OFFSHORE STRUCTURES, ICE LOADS, FLOATING ICE, ICING, ICE PILEUP, FLOODING, LABORATORY TECHNIQUES.

The discovery of offshore oil in ice-infested waters has caused major concern to the design engineers

Some of the problems associated with offshore structures are ice forces, ic ng. and associated with offshore structures are ice forces, ic ng, and pile-up. Laboratory facilities have and will continue to solve many of the ice problems. The ice problem at navigation locks, for example, has been solved primarily due to laboratory studies. Also, the results of ice forces due to ice uplift have been virtually eliminated by controlled studies. Laboratories are becoming larger and more sophisticated. This should result in an increase in laboratory studies and a decrease in field studies. Solutions will come faster because conditions can be precisely controlled

EMATICS).

A dynamic constitutive law is used to study the response of medium-denuty snow to shock waves. The results show good correlation between theory and experiment, except for low-intensity shocks which produce small permanent density changes. In this case the validity of the data is questioned, although further experimental work is needed to settle this question. The results of this work also partially explain why snow is so effective in absorbing energy associated with stress waves. This is felt to be due to the work-hardening characteristics of snow

MP 1307 APPLICATION OF RECENT RESULTS IN FUNCTIONAL ANALYSIS TO THE PROBLEM OF WETTING PRONTS.

Nakano, Y., Apr. 1980, 16(2), p.314-318, 16 refs

SOIL WATER MIGRATION, SOIL PHYSICS, BOUNDARY VALUE PROBLEMS, SEEPAGE, POROUS MATERIALS, WETTABILITY, ANAL-YSIS (MATHEMATICS).

Traditionally, in hydrology and soil physics, wetting fronts appearing in porous media described by Darcy's law have not generally been considered to be singular surfaces. Some recent results from functional analysis are presented as evidence. * pporting the viewpoint that wetting fronts with a finite propagating speed generally are singular surfaces.

MP 1308 TIME-PRIORITY STUDIES OF DEEP ICE CORES.

Gow, A.J., May 1980, GD-8, p 91-102, 18 refs 34-4030

ICE CORES, DRILL CORE ANALYSIS, ANTARC-TICA—BYRD STATION.

TICA—BYRD STATION.

Both the Greenland and Antarctic ice sheets have been successfully core-drilled to bedrock, 1390 m at Camp Century, Greenland in 1966 and 2164 m at Byrd Station, Antarctica in 1968. Core and borchole studies at both sites have revealed a wealth of interesting results, especially at Byrd Station where extensive studies of cores were begun as soon as they were pulled out of the drill hole. Continuing investigations of these Byrd Station drill cores, including recent observations of apparent widespread recrystallization in certain sections of ice core, further confirm the importance of initiating as many studies as possible at the drill site. Any list of the studies that should be conducted on deep cores must recognize two kinds of research. I) those studies of a time-priority nature that must be initiated as soon as cores are pulled to the surface and, 2) other essential studies in which relaxation of the ice is not a factor. These latter studies can generally be deferred until cores are transported to more permanent storage facilities outside Antarctica. ed to more permanent storage facilities outside Antarctica

FROST ACTION, FROST HEAVE, ICE NEEDLES. SOIL WATER MIGRATION, SOIL TESTS.

SOIL WATER MIGRATION, SOIL TESTS.

A method is described for consenient study of frost action including soil heaving and needle ice formation. The apparatus is simple and small and the procedure requires only 25 cu cm soil specimens. The method could be useful for screening either large numbers or limited quantities of soils or soil additives for frost susceptibility. The method described was used to perform a limited number of tests with several soils. The tests obtained action in the form of soil heave, ice heave, or ice needles, yielding maximum heights up to three to six times the initial 40-mm soil depth. Maximum growth rates were up to 1 to 1 mm hr for soil heaves and 3 to 7 or more mm h for ice heaves and ice needles. Initial trials showed that thickener additives and possibly other treatments can restrict frost exten and possibly other treatments can restrict frost zetion

FATE AND EFFECTS OF CRUDE OIL SPILLED ON SUBARCTIC PERMAFROST TERRAIN IN INTERIOR ALASKA

Johnson, L.A., et al, Mar. 1980, EPA-600/3-80-040, 128p., Refs. p.78-83 Sparrow, E.B., Jenkins, T.F., Collins, C.M., Davenport, C.V., McFadden, T.

OIL SPILLS, PERMAFROST THERMAL PROP-ERTIES, ENVIRONMENTAL IMPACT, THER-MAL REGIME, SUBARCTIC REGIONS, SEA SONAL VARIATIONS, EXPLRIMENTATION.

This study was conducted to determine both the short-and long-term effects of spills of hot Prudhoe Bay crude and long-term effects of spills of hot Prudhoe Bay crude oil on permafrost terrain in subarctic interior Alaska. Two experimental oil spills of 7570 liters (2000 gallons) each on 500 sq m test plots were made at a forest site underlain by permafrost near Fairbanks, Alaska. The oil spills, one in winter and one in summer, were conducted to evaluate their effect during these two seasonal extremes. Oil movement, thermal regime, botanical effects, microbiological responses, permafrost impact, and composition of the oil in the soil were monitored for two years.

FREE CONVECTION HEAT TRANSFER CHAR-ACTERISTICS IN A MELT WATER LAYER. Yen, Y.-C., Aug. 1980, 102(3), p.550-556, 17 refs.

MELTWATER, HEAT TRANSFER, CONVECTION, ICE WATER INTERFACE, WATER TEMPERATURE, TEMPERATURE EFFECTS, ICE MELTING, ANALYSIS (MATHEMATICS).

MELTING, ANALYSIS (MATHEMATICS).

An experimental study was conducted on the formation of a water layer containing a maximum density, its effect on the onset of convection, and the heat transfer characteristics of such a system This water layer was formed by one-dimensional melting (either from below or above) of a cylinder of bubble-free ice. The layer depth at the onset of convection was determined by locating the inflection point on the water layer depth versus time curve, and was compared with layer depth calculated from a linear stability analysis of an identical problem. The results were compared with the analytical work of Veronis and were found to be in excellent agreement. Formation of a constant temperature layer was observed by measuring the water temperature distribution as melting progressed. The constant temperature was found to depend on T(h) (warm plate temperature) for melting from below, progressed. The constant temperature was found to depend on T(h) (warm plate temperature) for melting from below, but had a weaker dependence for melting from above. The heat flux to the melting surface increased linearly with T(h) for melting from below, but had a weaker dependence for meiting from above. Non-dimensional mean temperature profiles of the water layer were found to be in good agreement with those by Adrian for melting from above. In the case of melting from below, the mean temperature profile also fell into a single line with a somewhat higher value in the convection layer.

ICE SHEETS, ICE CORES, RADIO ECHO SOUNDINGS, ICE PHYSICS, ANTARCTICA— FOLGER, CAPE.

FOLGER, CAPE.

In this paper, the measured physical properties of core to bedrock taken at Cape Folger, East Antarctica, are used to compute a depth-reflection coefficient profile for comparison with the observed radio-echo reflections. The measurements available on physical properties are density variations, bubble size and shape changes, and crystal fabric variations. In calculations to differentiate the effects of the physical peoperties, it appears that density variations account for the primary contributions to the calculated delectric property changes corresponding to the highest observed reflection coefficients. However, bubble changes alone can also account for reasonable, though lower, reflection coefficients at the depths corresponding to observed reflections. Crystal fabric variations correspondence between the depths of the bubble shape changes (which are definitely deformational features) and the depths of the density variations, and between both of these and the radio-echo layers, indicates that deformational recasts in the ice sheet's history are represented by the variations in physical properties and associated radio-echo records. ICE SHEETS, ICE LOADS, ICE PRESSURE, ICE STRENGTH, ANALYSIS (MATHEMATICS), PLATES.

PLATES.

A review of the buckling analyses of floating ice sheets is presented. The theory used is that of a beam or plate on an elastic foundation. For beams, the results for all possible boundary conditions are presented and discussed. For plates, results of numerical solutions for a semi-infinite plate loaded over part of its boundary are presented and discussed. One solution is presented for an infinite plate loaded radially at a hole in the plate. In addition, results for wedge-shaped beams and plates are presented and discussed. Wedge-shaped ice sheets frequently occur due to previous cracking in the ice. MP 1323

NESS, ELECTROMAGNETIC PROPERTIES. The frequency dependence of the polarization-irotation properties of fast ice upon radiowaves in the HF-VHF range were studied at Pt. Bartow, Alaska, in the early spring 1979. Five sites were investigated at frequencies betwee. 10 and 173 MHz and at each site cores were taken and then physical properties measured. The polarization was studied with a pair of crossed dipole antennas, one a transmitter, the other a receiver, both of which were rotated simultaneously as a finel unit. The recording was desired to a receiver. the other a receiver, both of which were rotated simultaneously as a fixed unit. This procedure was designed to produce a four-lobe closerleaf pattern with maximum coupling occurring when the antennas were aligned at 45 deg to the coasis direction. The results showed strongest polarization between about 35 and 65 MHz. Above this band the high deconductivity of the sea ice which was measured accounts for the lack of cross coupling, but it is not yet understood why the data was so create below this band. Experimental difficulties are also discussed.

SEA ICE, BRINES, ANISOTROPY, ELECTROMAGNETIC PROPERTIES, ICE OPTICS, ICE
WATER INTERFACE, DIELECTRIC PROPERTIES, ICE STRUCTURE, POLARIZATION
(WAVES), MATHEMATICAL MODELS

The contribution of brine layers to observed reflective amsotropy of sea see at 100 MHz is quantitatively assessed. The sea see is considered to be a stratified, inhomogeneous, anisotropic diefective consisting of pure we containing ordered

arrays of conducting inclusions (brine layers). Below the transition zone, the ice is assumed to have constant azimuthal c-axis orientation within the horizontal plane, so the orientation of brine layers is unaform. The brine layers are also assumed to become increasingly well-defined with depth, since adjacent brine increasing temperature. A theoretical explanation for observed reflective anisotropy is proposed in terms of anisotropy entertain anisotropy and brine layer geometry are linked to anisotropy in the complex dielectric constant of sea ice. Subsequently, a numerical method of approximating the reflected power of a plane wave pulse incident on a slab of sea ice is presented and used to show the contribution of the above effects to the observed reflective anisotropy.

MP 1326 POINT SOURCE BUBBLER SYSTEMS TO SUP-

PRESS ICE. Ashton, G.D., Nov. 1979, 1(2), p.93-100, For another version see 33-4224. 8 refs.

J3-695 ICE REMOVAL, BUBBLING, ICE MELTING, HEAT TRANSFER, ICE COVER THICKNESS, AIR TEMPERATURE, WATER TEMPERATURE, MATHEMATICAL MODELS.

MATHEMATICAL MODELS.
An analysis of a point source bubbler system used to induce local melting of an ice cover is presented. The analysis uses empirical results of bubbler plume experiments and impingement heat transfer results to determine the rate of melting at the underside of an ice cover. Through a simple energy budget analysis of the ice cover, the melting of the ice cover and resulting extent of open water are determined as a function of air temperatures, depth and air discharge of the source, and water temperature. The analysis leads to a numerical simulation and an example simulation is presented.

TEMPERATURE EFFECTS, PHASE TRANSFOR-MATIONS, SOIL FREEZING, CLAYS, IONS, LOW TEMPERATURE TESTS.

Prior work has revealed the existence of one or more low temperature phase changes in clay water systems in the temperature range 200C to arout 500C. The number and the temperatures at which these phase changes appear seems to be associated with the type of exchangable 1001(s) and the number and nature of individual water domains present. In this paper, we report the results of low temperature differential calorimetry on monimorphonic and nontrosite clays at high water and high salt enotests. The presence of electrolytes at high concentration is shown to have a very marked effect. The low temperature phase changes are completely absent at high electrolyte concentrations in these clay water systems. The presence of electrolytes also was observed to have a distinctive effect on the shape of the initial freezing peak associated with see segregation. Prior work has revealed the existence of one or more lo

TY, ANALYSIS (MATHEMATICS).

The mixing theory of Polder and Van Santen is revised for application to three cases of wet snow. The dielectric constant is calculated for a range of liquid contents and porosities. These calculated values compare favorably with experimental data for the two cases in which data are available. The application to a snow cover with a heterogeneous distribution of liquid is discussed. The possibility of applying this theory to calculate the imaginary part of the dielectric constant, must be explored further. constant must be explored further.

SEA ICE, DRIFT, ICE WATER INTERFACE, BOUNDARY LAYER, MATHEMATICAL MOD-ELS, VISCOUS FLOW.

ELS, VISCOUS FLOW.

The finite-element formulation of a linear viscous sea ice model has been presented. The temporal ice acceleration term is included in the momentum equations in order to compute nonsteady ice drift rates. This model is applied to the Strait of Belle Isle, where strong tidal streams move the pack ice back and forth. Using idealized sinusoidal variations of the tidal streams, it is found that the time lag between the water and the ice velocities is dependent upon the viscosity parameters. These results indicate that the ice is not drifting freely and the boundary layer near the shore affects the ice movement in the Strait. The viscosity parameters used in this study ar aliall in order to simulate a reasonable time lag between the ice and water velocities. The high shearing near the shores necessitates low viscosities proper simulation of the flow of pack ice in the Strait.

ICEBERG WATER: AN ASSESSMENT. Weeks, W.F., 1980, Vol.1, p.5-10, 27 refs. 35-2197

ICEBERGS, WATER SUPPLY, ICEBERG TOW-

INO.

This review of the idea of using icebergs as a source of fresh water starts with a historical survey covering the period up to April 1980 and stresses how the approach to the subject has changed with time.

Both the progress that have cuther just surfaced or never been adequately addressed are discussed. It is concluded that successful tows to Australia, clearly the most considerable proteins addressed and the problems. concluded that successful flows to Austrian, clearly the most consulty-reached potential delivery site, are possible if tecbergs can retain their structural integrity during tows in high seas and if schemes can be developed for docking and processing. Tows to sites in the northern hemisphere such as Saudi Arabia and California are significantly more difficult and will remain so until an effective and operationally-realistic method is developed for isolating the teckerg from the warm sea-water that will be encountered during part of the tow. Whatever the ultimate resolution of the iceberg-water proposal

may be, research stimulated by this idea has already resulted in a major improvement in our knowledge of the life and time of real icebergs in real oceans. (Auth.)

ACOUSTIC EMISSION RESPONSE OF SNOW. St. Lawrence, W.F., 1980, 26(94), p.209-216, 10 refs., In English with French and German summaries.

SNOW ACOUSTICS, AVALANCHE TRIGGER-ING, AVALANCHE FORMATION, STRESS STRAIN DIAGRAMS, RHEOLOGY, ULTRA-SONIC TESTS, MATHEMATICAL MODELS.

SUNIC TESTS, MATHEMATICAL MODELS.
In this work a model of the ultrasonic acoustic emission response in snow is developed. The model derived considers the acoustic emission response in snow as a function of stress and strain. It is suggested that the acoustic emission activity in snow is a quantitative indication of the creep rupture taking place in the material. The governing differential equation is developed; an example is then presented that considers the applicability of this equation to the release of certain types of avalanche.

MP 1367 PROPAGATION OF STRESS WAVES IN AL-PINE SNOW.

35-2366 STRESSES, SHOCK WAVES, SNOW DENSITY, WAVE PROPAGATION, SNOW PHYSICS, PRES-SURE, ANALYSIS (MATHEMATICS), ALPINE LANDSCAPES.

LANDSCAPES.

The propagation of pressure waves in low-density snow is investigated analytically to determine the variation of wave pressure and wave speed with density and frequency. The results show that, for pressure waves that produce finite volumetric deformations, both pressure jump across the wave and wave-speed increase with initial density and final density the pressure jump was also found to increase with the wave frequency if other parameters were held constant, although the dependence on frequency is not as strong as the dependence on the initial and final densities. The relationship between pressure jump and frequency implies that high-frequency waves would tend to dissipate more quickly than lower-frequency waves, although like pre jurc, the attenuation rate would not be strongly frequency dependent.

MP 1368 THERMODYNAMICS OF SNOW METAMOR-PHISM DUE TO VARIATIONS IN CURVA-

Colbeck, S.C., 1980, 26(94), p.291-301, 28 refs., In English with French and German summaries.

35-23/2
METAMORPHISM (SNOW), THERMODYNAM-ICS, SNOW THERMAL PROPERTIES, HEAT TRANSFER, VAPOR DIFFUSION, TEMPERA-TURE GRADIENTS, ANALYSIS (MATHEMAT-ICS), WET SNOW.

In the absence of imposed temperature gradients, the metamorphism of dry snow is dominated by the slow process of vapor diffusion between surfaces of different radii of curvature vapor diffusion between surfaces of different radii of curvature. This process is so slow in a seasonal snow cover (where temperatures normally change on the scale of hours or days) that vapor migration is usually dominated by the imposed temperat;—e gradient. Thus radius of curvature contributes to but does not control metamorphism except for short periods in very fresh snow. As opposed to dry snow, liquid-saturated snow (i.e. pore space filled by the melt) is metamorphosed by heat flow arising from relatively large temperature differences among the particles. Grain growth in liquid-saturated snow is rapid because of the large temperature differences at nearly constant liquid pressure. in hquid-saturated snow is rapid because of the large tempera-ture differences at nearly constant liquid pressure. In wet snow with low liquid content (2-5% by volume), grain growth is dominated by vapor diffusion (as in dry snow) so grain growth is much slower than under conditions of houid saturation

MATION OF SNOW. St. Lawrence, W F., et al, Jan. 1981, 4(1), p.3-14, 16

refs. Lang, T.E

35:2414 SNOW DEFORMATION, SNOW COVER STRUC-TURE, STRESS STRAIN DIAGRAMS, SNOW COMPRESSION, VELOCITY, SNOW ACOUS-TICS, ANALYSIS (MATHEMATICS)

In this paper a constitutive equation which describes the uniaxial deformation of snow is developed. The basic

assumption underlying this work is that the stress-strain response can be derived by considering the structure of the material. The equation which describes the plastic portion of the deformation is developed by considering the relationship between three fundamental variables: the mean specing between ince grains, the relatative velocity between grains, and the fraction of the total number of grains which participate in the deformation process. The mean distance between ice grains is determined by a stereological investigation of the snow structure, and the velocity component is found by empirically characterizing the relaxation of the snow. To determine the mobility of the ice grains acoustic emission data are used. An equation describing the pattern of acoustic emissions for constant rates of deformation is derived and applied to a number of tests. Combining the above variables produces a compressive and tensile constitutive equation which reflects the behavior of the snow under both uniaxial deformations. uniaxial deformations

CYCLIC LOADING AND FATIGUE IN ICE. Mellor, M., et al, Jan. 1981, 4(1), p.41-53, 4 refs. Cole, D.M.

35-2417

ICE CRYSTALS, DYNAMIC LOADS, ICE STRENGTH, STRESS STRAIN DIAGRAMS, FATIGUE (MATERIALS), ICE CREEP, TIME

FACTOR.

Isotropic polycrystalline ice was subjected to cyclic loading in uniaxial compression at -5C, with stress limits 0-2 and 0-3 MPa, and frequencies in the range 0.043 to 0.5 Hz. Stras-strain records showed hysteresis loops progressing along the strain axis at non-uniform retes. The effective secant modulus, which was about half the true Young's modulus, decreased during the course of a test. The elastic strain amplitude and the energy dissipated during a loading cycle both increased with increase of time and plastic strain amplitude and search as the second course which were identical in form to classical constant stress creep curves, with a small cyclic alternation of recoverable strain about the mean curve. The results of the tests suggest that maximum resistance under compressive cyclic loading occurs at an axial plastic strain of about 1%, which is essentially the same as the failure strain for ductile yielding under constant stress and under constant strain-rate.

, ICE COVER EFFECT, CLIMATE, RNE PHOTOGRAPHY, PHOTOIN-SEA ICE. SPACEBORNE SPACEBORNE PHOTOGRAPHY, PHOTOIN-TERPRETATION, HEAT LOSS, MICROWAVES. Ice extent charts prepared from satellite images by the U.S. Naval Fleet Weather Facility and passive microwave emission data from the Nimbus V satellite were examined for the winters of 1973 and 1974 to determine the variation between the two years of the heat loss by the atmosphere because of variations in sea ice extent and concentration. The microwave data indicate that most of the ea within the ice edge is less than 80% ice covered even during the coldest part of the year, probably because of ocean currents, waves, and swell, and convergence and divergence in the atmospheric forcing fields. Since the winter heat and moisture transports from open water are about two orders of magnitude larger than from an equal area of sea ice, even small areas of open water within the ice edge can greatly affect the energy exchange. These n-w data are compared with the assumption of 100% ice cover within the ice edge and with previously assumed mean values for the total area covered by ice in calculating the heat lost by the atmosphere during the winter period in high southern latitudes. A rapid decrease in sea ice extent observed during the winter of 1973 is correlated with a nearly real-time adjustment by the atmosphere to the change in the heat lost caused by the removal of the ice. This example indicates that sea ice dynamics is influential not only in long-term climate, but in synoptic-scale weather patterns as well. TERPRETATION, HEAT LOSS, MICROWAVES.

MISGIVINGS ON ISOSTATIC IMBALANCE AS A MECHANISM FOR SEA ICE CRACKING. Ackley, S.F., et al, Sep. 1976, No.33, p.85-94, 12 refs. Hibler, W.D., III, Kugzruk, F.K.

31-450

SEA ICE, ICE CRACKS, ISOSTASY, ICE PHY-SICS, ICE DENSITY.

In the AIDIEX ice pack model the formation mechanisms for ice cracks are ignored because of the many processes by which cracks may form. The authors question this concept and particularly the mechanism of isostatic imbalance. They cite the Young's modulus used in the AIDIEX model as being not representative of sea ice and that beam experiments in static tests lead them to question the validity of a purely clastic analysis.

ICE SHEETS, ICE CRYSTAL STRUCTURE, RHEOLOGY, ICE DEFORMATION, ANTARCTICA—BYRD STATION.

RHEOLOGY, ICE DEFORMATION, ANTARC-TICA—BYRD STATION.

Crystalline textures and fabrics of ice cores from the 2,164-m-thick ice sheet at Byrd Station, reveal the existence of an anisotropic ice sheet. A gradual but persistent increase in the c-axis preferred orientation of the ice crystals was observed between the surface and a depth of 1,200 m. This progressive growth of an oriented crystal fabric is accompanied by a twentyfold increase in crystal size between 56 and 500 m, followed by virtually no change in crystal size between 600 and 1,200 m depth. A broad vertical clustering of c axes develops by 1,200 m. Between 1,200 and 1,300 m, the structure transforms into a fine-grained mosaic of crystals with their basal glide planes now oriented substantially within the horizontal. This highly oriented fine-grained structure, which persists to 1,800 m depth, is compatible only with a strong horizontal shear deformation in this part of the ice sheet. Rapid transformation, accompanied also by the growth of very large crystals, is attributed to the overriding effect of relatively high temperatures in the bottom layers of old ice at Byrd Station rather than to a significant decrease in stress The zone of single-maximum fabrics between 1,200 and 1,800 m also contains numerous layers of volcanic dust which appear to be actively associated with shearing in the ice sheet. Some slipping of ice along the bed rock are also major contributors to the flow of the ice indicate that plastic deformation (intracrystalline glide) in the zone of strong single-maximum fabrics and movement of ice along discrete shear planes situated well above bed rock are also major contributors to the flow of the ice sheet. (Auth. mod.)

ECOLOGICAL AND ENVIRONMENTAL CONSEQUENCES OF OFF-ROAD TRAFFIC IN NORTHERN REGIONS.

Brown, J., Surface Protection Seminar, Anchorage, Alaska, Jan. 19-22, 1976. Proceedings. Edited by M.N. Evans, Anchorage, Alaska, Bureau of Land Management, Aug. 1976, p.40-53, 19 refs.

THAWING.

The consequences of off-road activities depend on when the activity occurs (summer vs. winter), the degree of impact, the nature and response of the underlying permafrost to the surface modification, and the rate at which the damaged environment will recover. Regulations based on a knowledge of the environmental variables and how they react to impact are required to minimize impact in these areas which are sensitive to human and natural perturbations. We should not underestimate the requirement for good environmental information and adequate resource mapping as first, necessary steps.

VEHICLE FOR THE FUTURE.

VEHICLE FOR THE FOLUKE.
Snughter, C.W., Surface Protection Seminar, Anchorage, Alaska, Jan. 19-22, 1976. Proceedings. Edited by M.N Evans, Anchorage, Alaska, Bureau of Land Management, Aug. 1976, p.272-279, 5 refs. 31-1111

January and the control of the contr tion, operator sensitivity, and access priorities also affect surface damage. More important than vehicle design and selection are the management decisions to be made concerning regulation of off-road travel.

ELECTRON MICROSCOPY, CRYOGENIC SOILS, MORAINES, SOIL COMPOSITION, GRAIN SIZE, WEATHERING, ANTARCTICA— VICTORIA LAND.

The textures of moraine soils from southern Victoria Land were investigated, using a scanning electron microscope fitted with an energy dispersive X-ray analyzer. Electron micrographs of soil grains from lower Wright Valley showed sharpedges and smooth surfaces, indicating a low degree of mechanical and chemical weathering. The soil grains were 11% quartz and 4% magnetite Chlorides were found on 17% of the soil grains. By contrast, electron micrographs of soil grains from the Beacon Valley showed rounded grains indicating a high degree of mechanical and chemical weathering. The soil grains were 20% quartz. Rhombohedral contracts of SOM were found on 60% of the soil grains. The textures of morainic soils from southern Victoria Land ing The soil grains were 20% quartz. Rhombohedral cr, stals CaSO4 were found on 60% of the soil grains Chlorides were found on 30% of the soil grains Chlorides were found on 30% of the soil grains. Because of the high degree of weathering, it was concluded that the morainic soils from the Beacon Valley are much older than those of the lower Wright Valley.

33-2314 WINDOWS, COLD WEATHER CONSTRUC-TION, WEATHERPROOFING, MOISTURE, CLI-MATIC FACTORS, COUNTERMEASURES.

Extreme cold causes heavy buildup of frost, ice and condensa-tion on many windows. It also increases the incentive for improving the airtightness of windows in Alaska to avoid moisture accumulation in homes and barracks. We base moisture accumulation in homes and barracks. We base our conclusions on a two-year study of Alaskan military bases that included recording humidity and temperature data, observing moisture accumulation on windows and measuring airtightness with a fan pressurization device Our study shows that tightening Alaskan windows to permit only 30% of the air leakage allowed to current American standards for window airtightness is economically attractive.

WASTE TREATMENT, WATER TREATMENT, PLANTS (BOTANY).

PLANTS (BOTANY).

Aquaculture systems for wastewater treatment often include plants, finned fish, animals and microorganisms in various combinations in aquatic settings such as ponds, marshes, bogs and other forms of wetlands. Natural settings have often been used in the past but there is a trend toward constructed systems which permit more reliable management at higher rates of treatment. This paper evaluates the potential for application of aquaculture concepts for wastewater treatment in cold climates. Constructed wetlands and the enclosed high rate processes offer the most promise of the concepts considered. Systems based on plants are more efficient, require less area and are easier to control than concepts involving higher forms of animals.

HUMAN FACTORS, STANDARDS.

Air quality measurements were made for both gases and particulates at several locations near Fairbanks, Alaska, during winter. The results indicated that carbon monoxide levels downtown frequently exceeded air quality standards and were significantly elevated at more rural locations up to 22 km from the downtown area. High levels were found to be associated with temperature inversions. Nitric oxide levels were measured and found to range from less than 50 to over 500 parts per billion (ppb) downtown. Levels of 1 to 68 ppb were measured in a more rural location. The major source of both CO and NO at Fairbanks was found to be auto exhaust. Levels of particulate lead in the downtown area were found to exceed Federal Standard for all 4 winter months. Lead levels at the more rural

site were only about one-tenth those of downtown and did not exceed standards

The Alasian Projects Office of Cold Regions Research and Engineering Lauratory has been studying the forces imposed on the Yi kon River bridge by ice during breakup. The study inverved four consecutive breakups from 1977 thru 1950. Forces have been measured using load cells mounted on the front of the auraber 5 pier to intercept the ice as it strikes the pier. Accelerometers mounted on piers support 4 and 5 were used to measure the response of on the front of the number 5 pier to intercept the ice as it stitkes the pier. Accelerometers mounted on piers number 4 and 5 were used to measure the response of the pier to the ice impacts. Ce-libration procedures were employed to determine a transfer function which relates the accelerations to the arplied forces. Ice thicknesses were measured using stort pulse radar techniques. River ice damaged or destroyed the first generation load cell designs, but some useful data was obtained before failure. Radar techniques show some promise for the measurement of ice thicknesses during breakup

FORMATION.

The techniques for analyzing velocity profiles should be carefully considered in shallow streams where the flow depth is less than 1 m. The two procedures, a) mean and maximum velocity determinations and b) intercept evaluation of log (depth)-velocity plots, yield different results for the various resistance coefficients and shear stress values. The mean-max-velocity method generally predicts higher values than the other and is recommended for shallow streams. The minimum distance from a boundary to the position of maximum velocity for a good velocity profile appears to be roughly 15 to 20 cm with a 5 cm diameter sensor

MARS (PLANET), SOIL WATER, ADSORPTION, WATER VAPOR, THERMODYNAMICS, SOIL MICROBIOLOGY, TEMPERATURE EFFECTS.

One of the scientific objectives of the Viking Mission to Mars was to accomplish an analysis of water in the Martian regolith The analytical scheme originally envisioned was severely compromised in the latter stages of the Lander instrument package design. The presence of a duncrust at one of the Lander sites is taken as possible evidence for the presence of hygroscopic minerals on Mars. The demonstrated presence of atmospheric water vapor and thermodynamic calculations lead to the belief that adsorbed water could provide a relatively favorable environment for endolitic organisms on Mars similar to types recently discovered in the dry antarctic deserts

MP 1410 ESTIMATION OF HEAT AND MASS FLUXES OVER ARCTIC LEADS.

POLYNYAS, SEA ICE, HEAT TRANSFER, MASS TRANSFER, TURBULENT EXCHANGE, HEAT FLUX, ANALYSIS (MATHEMATICS).

FLUX, ANALYSIS (MATHEMATICS).

Recent work on the turbulent transfer of scalar quantities following a step increase in the surface value of the scalar is directly applicable to the problem of estimating heat and mass transfer from Arctic leads in winter. With the transfer relations, turbulent fluxes can be computed from standard meteorological observables; and from the Nusselt number equality, partitioning of the turbulent fluxes can be evaluated —in particular, the partitioning of the heat flux between sensible and latent components.

PILES IN PERMAFROST FOR BRIDGE FOUN-

STREAMS.

This cooperative research study has focused considerable attention on the ground temperatures existing beneath and adjacent to streams in permafrost areas. An appreciation of the changes in the thaw area beneath the stream, both at the time of construction and for the life of the structure, is essential to proper string of the bridge foundation. Location of abutments and piers outside of the potential thaw zone of the stream, or penetration at the most advantageous points to depths sufficient to achieve the required bearing capacity, is essential.

The design of piles based on depth of embedment, affrect acregith or dynamic driving formulas in frozen soils is of title value if the permafrost condition is later destroyed. Emphasis must be placed on retaining the original permafrost conditions and providing for frost action.

UNFROZEN WATER CONTENTS OF SUBMA-RINE PERMAFROST DETERMINED BY NU-CLEAR MAGNETIC RESONANCE.

Tice, A.R., et al, International Symposium on Ground Freezing, 2nd, Trondheim, Norway, June 24-26, 1980. Preprints, Trondheim, University, Norwegian Institute of Technology, 1980, p.400-412, 10 refs. Anderson, D.M., Sterrett, K.F.

30-32 SUBSEA PERMAFROST, UNFROZEN WATER CONTENT, MELTING POINTS, NUCLEAR MAGNETIC RESONANCE, TEMPERATURE EFFECTS, TEMPERATURE MEASUREMENT, DRILL CORE ANALYSIS.

Prior work resulted in the development of techniques to measure the unfrozen water contents in frozen soils by nuclear magnetic resonance (NMR) It has been demonstrated that NMR is a promising new method for the determination of phase composition (the measurement of unfrozen water content as a function of temperature) which circumvents many of the limitations inherent in the adiabatic and isothermal calorimetric techniques. The NMR technique makes it possible, in a non-destructive, non-intrusive way, to explore hysteress by determining both cooling and warming curves. Corrections are made for dissolved paramagnetic impurities which have the effect of increasing the signal intensity at decreasing temperatures. The results demonstrate that NMR techniques can be effectively utilized both at and below the melting point of ice in frozen soils and that accurate melting points (freezing point depressions) can be determined. Prior work resulted in the development of techniques to determined.

MP 1413 COST-EFFECTIVE USE OF MUNICIPAL WAS-TEWATER TREATMENT PONDS.

Reed, S.C., et al, Session on Appropriate Technology in Water Supply and Waste Disposal at the ASCE National Convention, Chicago, Illinois, Oct. 16-20, 1978. ASCE preprint 3435, New York, American Society of Civil Engineers, 1979, p.177-200, 23 refs. Hais, A.B. 35-2751

WASTE TREATMENT, WATER TREATMENT, PONDS, COST ANALYSIS, STATISTICAL ANALYSIS, DESIGN.

ANALYSIS, DESIGN.

Treatment ponds are a cost-effective alternative for municipal wastewater treatment. When compared to other secondary treatment alternatives, ponds are generally the least costly, require less energy and less skilled operational attention. They can be designed to consistently meet BOD removal requirements and can achieve significant reductions in nutrients, bacteria, and viruses.

POROUS MATERIALS, WATER FLOW, AIR FLOW, WAVE PROPAGATION, HYDRAULICS, BOUNDARY LAYER, WETTABILITY, ANAL-YSIS (MATHEMATICS).

A traveling wave solution was derived for the problem of simultaneous flow of water and air through homogeneous porous media.

The properties of the solution generally depend upon the hydraulic characteristics of a given problem. The properties of the solution are presented for a specific case in which the hydraulic characteristics are given in specific functional forms for this specific case a singularity occurs in the solution of both a saturated-unsaturated boundary and a wetting front. Some applications of the solution are discussed. and a wetting front. are discussed.

SEA ICE DISTRIBUTION, WEATHER, WIND (METEOROLOGY), OCEAN CURRENTS, AN-TARCTICA.

Within the last decade data on sea ice from satellite coverage have become available for the Southern Hemisphere. The data record is reviewed with some consideration given to the different mechanisms of ice advection by wind forcing, thermodynamic growth, and ocean mixing. These mechanisms control the ice edge around Antarctica and lead to the characteristic advance-retrieat relationships for the Weddell Sea, East Antarctica, and the Ross Sea. Recent statistical and function (EOF) analyses have shown two primary areas of higher annual variation of sea ice conditions which are presumed to be of dynamic (winds and currents) rather than thermodynamic (temperature) origin. It is possulated that atmospheric forcing of the sea ice system causes changes in air-sea energy transfers that then drive the atmosphere to its own anomaly condition. Further correlations that may define the mechanism of sea ice response to the forcing fields and supply stronger evidence of weather and climate responses to ice variations, may be available by analysis of the Global Weather Experiment drifting buoy data obtained during 1979 (Auth mod)

MP 1427 SEA-ICE ATMOSPHERE INTERACTIONS IN THE WEDDELL SEA USING DRIFTING RUOVS

Ackley, S.F., 1981, No.131, Sea level, ice and climatic change proceedings of the symposium held 7-8 Dec 1979, edited by I. Allison, p.177-191, 23 refs 35-3029

SEAICE, ATMOSPHERIC CIRCULATION, PACK ICE, ATMOSPHERIC PRESSURE, DRIFT, AIR TEMPERATURE, WIND FACTORS, WEDDELL

Air-dropped data buoys were placed on the Weddell Sea pack ice during December 1978 These buoys transmit

information via the NIMBUS satellite giving data on their position, surface pressure, and surface temperature. The velocities of four buoys during fall showed values up to 40 cm/s (35 km/day). The highest sustained velocities appear to coincide with sudden drops in air temperature. Schwerdifeger (1979) has postulated a model of winds in the western Weddell Sea dominated by thermal rather than pressure gradient forces due to the damming of cold air from continental barrier and katabatic winds against the mountains of the Antarctic Peninsula. This model is examined to explain the drift rates associated with cold air outbreaks. (Auth)

NAVIGATION.

A 19-year record of annual closing and opening dates of the Lake Champlain ferry season was found to accurately approximate the freeze-over and breakup dates for the ferry crossing area between Gordon Landing, Vermont, and Cumberland Head, N Y. These lake navigation records, when compared statistically with the lake's wintertime thermal structure and climatological data for the same years of at nearby Lake Champlain locations, allowed accurate predictions of ice formation. From nearby, air temperature records. nearoy Lake Champiani notations, allowed accurate predictions of ice formation From nearby air temperature records, cumulative freezing degree-day (C) curves were plotted for each year of record and ice formation dates and standard deviations were predicted with considerable accuracy Several methods of predicting ice formation on Lake Champian were attempted The most accurate approach used a combination of water temperatures and freezing degree-days. A method of predicting ice growth rates is shown and the influence of wind speed on ice cover formation and prediction on a large body of water such as this is also discussed.

SEA ICE, DRIFT, BIOMASS, WEDDELL SEA.

SEA ICE, DRIFT, BIOMASS, WEDDELL SEA. The purpose of this study was a investigate several characteristics of Weddell Sea pack her that may affect the relative roles of dynamics and thermodynamics of pack hee development in this region. The physical and structural properties of the pack here were surveyed using core samples. Significant amounts of frazil here were found. If this formation of frazil here is as widespreau as suspected, then the role of deformation (the opening and cloung of leads and polynyasis may have a greater role in the formation of Weddell Sea pack here than similar processes do in the arctic pack. I our data buoya were deployed. The initial locations are shown, and the studies for which the buoy data will be used are discussed. Observations during the cruise confirmed the ubiquitous presence of algee in nearly all forms of ree sampled and point to close links between pack her formation and enhanced algal production.

A procedure is described for monitoring the microfracturing of ice plates subjected to constant loads. Sample time records of fresh water ice plate deflections as well as corresponding total acoustic emission activities are presented. The linear clastic as well as viscoelastic response for a simply supported rectangular ice plate is given in the present investigation acoustic emission methods are used to study the microfracturing activity in polycrystalline ice subjected to flexural loads. The relationship between acoustic emissions and the time dependent inclastic flexural deformation in ice is studied.

Furthermore, the influence of the magnitude of the applied load and the rate of deformation on cracking activity is explored.

SOME APPROACHES TO MODELING PHASE CHANGE IN FREEZING SOILS. Hromadka, T.V., II, et al, Apr. 1981, 4(2), p.137-145,

Guymon, G.L., Berg, R.L. 35-3670

SOIL FREEZING, PHASE TRANSFORMATIONS, THERMAL REGIME, UNFROZEN WATER CONTENT, SOIL WATER, MATH-EMATICAL MODELS.

EMATICAL MODELS.

Phase change effects associated with freezing soils dominate the thermal state of the soil regime. Furthermore, freezing of soil water influences the soil moisture regime by providing a moisture sink which tends to draw mobile soil moisture to freezing fronts. Consequently, it is critical to general purpose models that soil water phase change effects and the interrelated problem of enarmating the moisture sink effects (i.e., conversion of liquid water to ice) be accurately modeled. The choice of such a model will not only influence the precision of simulated temperatures and water contents in a freezing soil, but will also have a significant impact on computational efficiency. A review of several current models that assume unfrozen water content is functionally related to subfreezing temperatures indicates that within

a freezing soil the soil water flow model and heat transport a freezing soil the soil water flow model and next transport model narameters are restricted in spatial gradients according to the spatial gradient of modeled unfrozen water content. A freezing soil model based on the concept of sothermal phase change of soil water is proposed as an alternative

CYLINDRICAL PHASE CHANGE APPROXYMA-WITH EFFECTIVE THERMAL DIF-FUSIVITY.

Lunardini, V.J., Apr. 1981, 4(2), p.147-154, 13 refs.

PHASE TRANSFORMATIONS, FREEZE THAW CYCLES, THERMAL DIFFUSION, PERMA-FROST HEAT BALANCE, LATENT HEAT, PIPES (TUBES), ANALYSIS (MATHEMATICS).

(TUBES), ANALYSIS (MATHEMATICS).

No exact, general, solution exists for phase change in a cylindrical geometry. In fact, even approximate solutions are rare and limited in applicability. The use of the effective thermal diffusivity concept has allowed a closed form approximate solution to be generated for phase change around a circular cylinder in an indefinite medium. The effective diffusivity method permits solutions to be found for phase change problem amalogous to the phase change problem. Phase change problems are often intractable with the usual mathematical methods. The cylindrical formulae given here are shown to be of acceptable accuracy, for most engineering purposes, over a wide range of parameters. No other simple, closed form, approximation is known for the cylindrical system. Although the accuracy of the effective diffusivity method has been demonstrated for the cylindrical geometry, application to other geometries must be verified.

COASTAL-INLAND DISTRIBUTIONS OF SUM-MER AIR TEMPERATURE AND PRECIPITA-TION IN NORTHERN ALASKA.

Haugen, R.K., et al, Nov. 1980, 12(4), p.403-412, 22

35-3196 TUNDRA, PRECIPITATION (METEOROLOGY), AIR TEMPERATURE, SHORES, LONG RANGE FORECASTING, WIND FACTORS, UNITED STATES—ALASKA—NORTH SLOPE

STATES—ALASKA—NORTH SLOPE.

Using data from summer air temperature stations from the inland tundra to the immediate coastal area, regression analyses of the air temperature data from 1975 to 1978 were used to predict temperature values across the Alaskan Arctic Coastal Plain based upon latitude and longitude. This provides the best approximation of average values based on existing data. Mean monthly temperature, mean daily range of temperature, and thawing-degree days all increase with distance from the coast. The estimated July normal for Atkasook, 48 km south of the coast, is 3.7 C, while the established 30-yr normal for Barrow, on the coast, is 3.7 C. The July average temperature 6 km due south of the open water of Prudhoe Bay is 2 C higher than on the immediate coast. Within the area under the dominant influence of the sea preceive, regression analyses suggest a more precise relationship between air temperature and distance along the prevailing wind vector (N75 E) than between temperature and distance due north to the sea. due north to the sea.

MODELING NITROGEN TRANSPORT AND TRANSFORMATIONS IN SOILS: 1. THEORETICAL CONSIDERATIONS.

MATHEMATICAL MODELS.

A numerical model was developed to simulate water and nitrogen transport and transformations through water-unsaturated, multilayered soil profiles

The nitrogen transformation processes considered were nitrification, dentification, immobilization, mineralization, and ionic exchange of ammonism.

Plant uptakes of water and nitrogen were also included An explicit-implicit finite difference approximation method was used to salve the nitrogen transport and transformation. An explicit-imputed timite enterence approximation memors was used to solve the nitrogen transport and transformation equations simultaneously with the water flow equation. Model evaluation and sensitivity analysis for a wide range of values for the rate of nitrification, distribution coefficient for ammonium exchange, and rate of N uptake were investigations. (Auth.)

SOIL CHEMISTRY, NUTRIENT CYCLE, TRANS-FORMATIONS, WASTE TREATMENT, WATER TREATMENT, IONS, MODELS.

The nitrogen model described in Part I was evaluated using experimental data from a greenhouse lysimeter study for

two soils, Windsor sandy loam and Charlton silt loam. Secondary treated waste water was applied to each soil at the rate of 3.8 centimeters twice weekly for 25 weeks. Furthermore, (15) N-enriched NH4 cation-N was applied at the beginning of the experiment, in one waste water application. A mixture of grasses was grown on each lysimeter and was harvested every 2 to 4 weeks. Solution samples were collected and analyzed for N,and the soil water pressure head was monitored frequently at different soil depths. Model predictions agreed well with pressure head data with depth and time, at well as gravimetrically determined soil water content with depth for the two soils. (Auth. mod.)

MEN1. The concentrations of dissolved inorganic phosphate (DIP) in soil solution collected at 0.8 and 1.6 m in soils which had received municipal waste water for 4 and 13 years ranged from 7.3 to 13.9 microgram P/ml. In some cases, these concentrations were higher than that in the added waste water. Sorption studies indicated that the ability of soils from the control site to remove added P from solution was low. Waste water addition caused a substantial decrease in the P sorption capacity of surface soils and a marked change in isotherm shape from a curvilinear to an essentially linear isotherm. a marked change in isotherm shape from a curvilinear to an essentially linear isotherm. Sorption capacity generally increased down the profile to 60 cm on the treated sites. Only a small proportion of the total P accumulated from mastic water addition was in the organic form. Large amounts of P were extractable by 0.01 M CaCl2, particularly in the upper 45 cm of the profiles receiving waste water. Although lack of crop removal of P and a high infiltration rate may be partly responsible for the poor performance of the Manteca system in terms of P removal from waste water, the very low P sorption capacity of the soil is regarded as the major factor.

ICE NAVIGATION, ICE CONTROL, RIVER ICE, ICE JAMS, ICE BOOMS, WATER LEVEL.
This paper presents a four-year summary of the main effects of the booms on ice and ship interaction and vice-versa. Throughout the four winter seasons, relatively small quantities of ice were lost over and between the booms. Ships usually slid through without influencing the boom force levels, although, at times, the changes they wrought could be large. One boom needed strengthening and artificial islands were added for ice stability upstream. These devices and frequent icebreaker operations were able to compensate for the ice movement caused by winter navigation in this area

36-8
FROZEN GROUND STRENGTH, SOIL CREEP,
STRESSES, SOIL TEXTURE, TRIAXIAL TESTS,
RHEOLOGY, TEMPERATURE EFFECTS,
ANALYSIS (MATHEMATICS).
Temperature dependences of the failure activation energy
of frozen soils in the temperature range from -0.55 to
-00C were studied The analysis was based upon experimental data on the long-term failure of six frozen soils
wanchester and Ottawa sands, Sufficied and Bat-Bayoss clays, Hanover
silt and Kelovey sandy loam The failure activation energy
was expressed as a function of the theological parameters
of the long-term strength equation in the form of the sum
of two components an initial value that is independent
of failure stress and a stress-dependent increment of the
activation energy. The analysis showed that the initial
value of the failure activation energy varied between the
limits of 10.4 and 19.4 kcal/mole, the variation of stressdependent increments was between 0.3 and 6.6 kcal mole,
and the sum varied from 12.9 to 19.7 kcal mole. The
smaller initial and sum values of the activation energy refer
to the clay soils and the greater values to the sandy soils

STRENGTH OF FROZEN SILT AS A FUNCTION OF ICE CONTENT AND DRY UNIT WEIGE.
Sayles, F.H., et al, International Symposium on Ground Freezing, 2nd, Trondheim, Noiway, June 24 26, 1980. Preprints, Trondheim, University, Norwegian Institute of Technology, 1980, p.109-119, 12 1ef3 Carbee, D.L.

36.9 FROZEN GROUND STRENGTH, GROUND WA-TER, WATER CONTENT, STRESS STRAIN DIA-GRAMS. COMPRESSIVE PROPERTIES. GROUND ICE, LOADS (FORCES), GRAIN SIZE GROUND ICE, LOADS (FORCES), GRAIN SIZE. A total of 45 unconfined compression tests were conducted on frozen specimens of remolded, saturated Fairbanks silt at dry unit weights ranging from 993 to 1490 kilograms per cubic meter with total water contents ranging from 0.28 to 0.58. The rate of strain was 0.005/s. Using the criterion that the ice matrix in the soil fractures at the first point of significant yield shown in the stress-strain curve, which occurs at less than 0.01 strain in this study, the "ice matrix strength" is shown to be nearly proportional to the volumetric ice content of the soil for these tests. The strength at 0.2 strain appears to be nearly independent of the dry unit weight and water content of the soil.

OVERCONSOLIDATION GROUND FREEZING. FERECTS OF

Chamberlain, E.J., International Symposium Ground Freezing, 2nd, Trondheim, Norway, June 24-26, 1980. Preprints, Trondheim, University, Norwe-gian institute of Technology, 1980, p.325-337, 10 refs.

WATER CONTENT, STRESSES, DENSITY
(MASS/VOLUME), SOIL STRUCTURE.

(MASS/VOLUME), SOIL STRUCTURE. Settlement of clay soils after freezing and thawing is the result of the suction forces that draw pore water to the freezing front. These suction forces cause an increase in the effective stress on the clay beneath the freezing front, and thus cause an overconsolidation of the clay. As these suction forces often exceed 1 atmosphere, their direct measurement is not easy. The volume changes resulting from the freezing and thawing of clays are related to the plastic limit and have been observed in the laboratory to eash high as 25%. If provisions are not made to account for these volume changes in a ground freezing project, considerable damage to structures can occur from settlement and the resulting stresses. the resulting stresses.

GY, ANTARCTICA—WEDDELL SEA.

Eight species of loricate choanoflagellates (Acanthoecidae) have been observed, by light and electron microscopy, in samples obtained from the Weddell Sea during the austral summer of 1977. The distribution of most species within the Weddell Sea was widespread. Habitats included the water column, the edge of (or ponds on) ice floes, and the interior of ice floes. The distributional, environmental, habitat, and/or morphological range of all previously described species is expanded Methods of variation of transverse costal diameters between genera may be potentially useful to the understanding of taxonomy and phylogeny of this family. PERIMENTATION, FATIGUE (MATERIALS). This paper describes a method of computing the ice force and response of the structure on the basis of information given for ice velocity and properties of ice and the structure. The method is a step-by-step procedure using mode shape analysis involving two basic phases. During the first phase the structure penetrates into the ice sheet until a random loading rate dependent ice strength is reached. The ice sheet then fails within an area with finite length. Both the penetration and the failed zone are assumed to depend linearly on force. The ice forces and structural responses have been computed for a test structure at the U.S. Army Cold Regions Research and Engineering Laboratory in Hanover, New Hampshire, and the results are found to be consistent with those actually measured in laboratory experiments.

FREZEUP.

Long-term, site-specific statistics on the summer recommittons in the Harmson Bay-Camden Bay area are presented in probabilistic terms. The statistics are based on twenty-three years of ice observations acquired by commercial ships and tecbreakers, ice reconnaissance flights, and various satellites. Data is given on breakup and freezeup dates, the first occurrence of open water, and the number of continuous and total open water days. The impact of the summer rec conditions on petroleum activities in the study area are also briefly discussed.

ANCY, VISCOSITY.

A sea ice model which employs a viscous-plastic constitutive law has been applied to the East Greenland area. The model is run on a 40-km spatial scale at 1.4 day time steps for a 60-day period, using forcing data beginning 1. October 1979. Preliminary results verify that the model predicts reasonable inkinesses and velocities well within the ice margin. Separate simulations show that thermodynamics only and free drift with thermodynamics produce inadequate results. In particular, the free drift simulation produces unrealistic ice trajectories with excessive drift toward the coast and unreasonable nearthore thicknesses. the coast and unreasonable nearshore thicknesses. The net results of these simulations tend to verify that internal

ice stress, thermodynamics, and ice import must be considered to properly model this region.

MP 1450 POOLING OF OIL UNDER SEA ICE.

Kovacs, A., et al. International Conference on Port and Ocean Engineering under Arctic Conditions, 6th, Québec, Canada, July 27-31, 1981. Proceedings, Québec, Canada, Université Laval, 1981, p.912-922,

TION, ENVIRONMENTAL IMPACT.

Ice thickness profiles were constructed for six fast ice locations in the vicinity of Prudhoe Bay, Alaska, using a radar echo sounding system. The sounding data revealed in detail the undulating relief of the bottom of the sea we in which oil could pool up if released under the ice. In general, ice bottom morphology was found to reflect variation of the surface snow cover thickness and ice deformation. However, at several sites the ice bottom relief could not be correlated with these factors. Slush ice accumulations of up to 0.5 m were apparently the cause of this bottom roughness. Estimates of the volume of oil that could pool up in the ice bottom relief range from 20,000 to 60,000 cu m/sq km. For undeformed fast ice with no bottom slush ice growth, the potential pooling capacity varied from about 10,000 to 35,000 cu m/sq km. The effect of slush ice relief and structure on potential under-ice oil pooling is for the most pait unknown.

Information on sea ice conditions in the Bering Strait and the icefoot formation around Fairway Rock, located in the strait, is presented. Cross-sectional profiles of Fairway Rock and the relief of the icefoot are given along with theoretical analyses of the possible forces active during icefoot formation. It is shown that the ice cover most likely fails in flexure as opposed to crushing or buckling, as the former requires less force Field observations reveal that the Fairway Rock icefoot is massive, with ridges up to 15 m high, a seaward face only 20 deg from vertical, and interior ridge slopes averaging 33 deg. The icefoot is believed to be grounded, and its width ranges from less than 10 to over 100 meters. (MATHEMATICS), OFFSHORE STRUCTURES.

EMATICAL MODELS, SOIL WATER.

An analytical procedure is developed for the determination of potentiometric head in nonhomogeneous aquifers. Both steady and unsteady flow conditions are considered. The analytical procedure is based upon the use of orthogonal functions. It consists essentially of assuming an appropriate orthogonal series for both the aquifer properties and the unknown potentiometric head. The technique is applied to several one- and two-dimensional flow problems where conditions are described by the linearized Boussinesq equation. The result of the analysis is the expression of potentiometric heads in analytic form. Subsequent use of Darcy's law yields accurate, analytic equations for the associated velocity fields. Such representations of the flow field are a potential benefit for prediction of mass transport in groundwater since benefit for prediction of mass transport in groundwater since velocity is known as a continuous function of space and time. Other useful features of the orthogonal series approach include its straightforward application. The approach is also shown to eliminate the introduction of discretization errors associated with the use of node systems which are required by many alternative numerical methods.

SEA ICE, GROUND ICE, ICE ELECTRICAL PROPERTIES, RADAR ECHOES, SUBSURFACE INVESTIGATIONS, WAVE PROPAGATION, ELECTRIC FIELDS, MATHEMATICAL MODELS, DIELECTRIC PROPERTIES.

ELS, DIELECTRIC PROPERTIES.

The propagation of subsurface radar pulses in complex dielectric media is studied numerically. The model waveform is a 10-ns sinusoidal cycle, and the media properties are similar to those of most ground or sea ice. When the real part of the dielectric permittivity is frequency independent and the imaginary part is dominated by the de resistivity, amplitudes of the positive and negative half cycles unbalance, and the sinusoidal zero crossing is delayed from as normal position. In these cases, if reflector depth is known, the dielectric constant can be intersured from the time delay of the leading edge of the signal, and the de resistivity can be estimated from a comparison of the input and output pulse power spectra. When dive-ciric permittivity is frequency dependent through a simple islazation process, sweeform distortion depends on relazation frequency. In addition, distortion depends on relaxation frequency. In addition, if reflector depth is known, the dielectric relaxation parameters may be estimated when the medium relaxation frequency lies above and below the major portion of the pulse bandwidth. respectively

JOI 127 FROST HEAVE, HEAT TRANSFER, SOIL WATER MIGRATION, FROST PENETRATION, TEMPERATURE EFFECTS, MATHEMATICAL

A one-dimensional model for simulation of frost heave in a vertical soil column is presented. The model is based on simultaneous computation of heat and moisture transport in a freezing or thawing soil. Thermal processes at the freezing front are approximated by a lumped isothermal approach. The model accurately simulates frost heave, soil pore-water pressures, and temperatures when compared soil pore-water pressures, and temperatures when compared with a laboratory freezing column; however, to achieve adequate correlation certain model parameters must be determined by calibration. Because the model, like the frost-heave process itself, is highly sensitive to environmental and soil parameters that are varieble in both time and space, purely deterministic simulations will not provide sufficiently accurate predictions. Consequently, further development of the model is required in order to include a statistical-probabilistic approach for estimating frost heave within specified confidence limits.

FROST ACTION, FROZEN GROUND MECHANICS, FREEZE THAW TESTS, SOIL WATER, SOIL TEMPERATURE, WATER CONTENT, MATH-EMATICAL MODELS.

The use of an instrumented soil column in tests to develop a mathematical mode of the frost-heave process is described. Tensiometers, heat-flo. meters, thermocouples, and electrical a manematical mode of the irost-neare process is ackerited resistivity gages were installed throughout a soil column filled with Fairbanks siit. Chena Hot Syrings siit, or West Lebanon gravel. The column was 100 cm long and about 14 cm in diameter. An open system was used and absorption was monitored during the freezing process. Tests were conducted by using a constant rate of frost penetration, a constant heat-flow rate, or three sequentially lower temperature step changes at the soil surface. The soil column has provided critical data for verification of a one-dimensional mathematical model for estimating frost heave. As more soils are tested, this equipment will assist in improving and developing algorithms for the mathematical model and the most critical parameters that affect frost heave in a given soil-eg, surcharge, free water level, and hydraulic conductivity. A procedure is also presented for determining the saturated and unsaturated hydraulic conductivity and moisture-retention characteristics of a soil.

COMPARATIVE EVALUATION OF FROST-SUSCEPTIBILITY TESTS. Chamberlain, E.J., 1981, No.809, p.42-52, 89 refs.

SOIL FREEZING, SOIL WATER, FROST RESIST-ANCE FROST HEAVE, GROUND ICE, FREEZE THAW TESTS, FROST ACTION, GRAIN SIZE, PARTICLE SIZE DISTRIBUTION.

Methods of determining the frost susceptibility of soils are identified and presented. More than 100 criteria were found, the most common were based on particle-size characterfound, the most common were based on particle-size characteristics. These particle size enteria are frequently aumation such as grain-size distribution, uniformity coefficients, and Atterberg limits. Other types of information, such as permeability, mineralogy, and soil classification, have also been required. More complex methods that require tests based on pore-size distribution, mosture tension, hydraulic conductivity, heave sixes, and frost heave have also been proposed. However, none has proved to be a universal test for determining the frost susceptibility oils soils. Based on this survey, four methods are proposed for further study: the U.S. Army Corps of Engineers Frost-susceptibility Classification Systems, the moisture-tension/hydraulic-conductivity test, a new frost-heave test, and the California bearing ratio after-thaw test.

SIMULATION OF THE ENRICHMENT OF AT-MOSPHERIC POLLUTANTS IN SNOW COVER

36-1866
FRAZIL ICE, ICE FOUMATION, ICE ACCRETION, ICE GROWTH, WATER FLOW, ICE COVER STRENGTH, RIVER ICE, NUCLEATING AGENTS, ICE BOOMS.

A preliminary investigation was made of the effect of frazil A preliminary investigation was made of the effect of frazilice on arrays of lines positioned in flowing water under uniter conditions. It was found that the lines would provide a stable basis for forming an ice cover on many stream reaches that would normally remain open because of high velocity and shyllow depths. Tests were conducted in a refrigerated frum, a d in small mountain rivers. Flume depths varied from 2-22 cm and river depths varied from 33-50 cm. Average flow velocities had a range of 0.06-8 m/s in the rivers. Frazilice would grow on a line quite rapidly achieving a disancter of 32 mm in 15 min, on a 32 mm late line in the flume. In the river, overnight accumulations reached 20 cm in depth. A few drag force measurements were made which yielded an average shear drag coefficient of 0.16. The results suggest methods of increasing our control over ice.

ONE-DIMENSIONAL TRANSPORT FROM A HIGHLY CONCENTRATED, TRANSFER TYPE

SOUT CE. O'Net., K. 1982, 25(1), p.27-36, With French, German and Ki secto summaries. 27 refs.

36-1862 HEAT TRANSFER, MASS TRANSFER, FLOW RATE, ANALYSIS (MATHEMATICS).

RATE, ANALYSIS (MATHEMATICS). In both heat and mass transfer, situations arise in which an entity considered as a source/sink has strength which can only be expressed in terms of an unknown rate of source—flow field transfer. This occurs when transfer between the source and medium is driven by a dependent variable difference which is unknown, because the responding medium value is unknown. Manifold mathematical completutes arise when in addition the source is highly concentrated spatially relative to the size of the overall domain. A 1-dim convective-diffusive transport equation suitable for this cause may be solved by simultaneous use of the Fourier transform and its inverse in the same equation, together with other transformation and manipulation. From the solution obtained for the case of constant source intensity, one may construct a general expression for the solution when source intensity varies arbitrarily in time. Explicit expressions are obtained for solution of the fundamental case of temporally sinusoidal source intensity.

An airborne spectroradiometer with 500 parallel channels has been used to monitor water quality in various water environments. Field experiments were run to test and evaluate the instrument's response to various amounts of suspended materials in water. Procedures were evaluated in the laboratory to separate the various components from the total reflected radiance and to correlate the spectral distribution of the subsurface reflectance to the organic/inforganic materials in the water. It was concluded that qualitative read quantitative measurement of turbidity within a water body is possible using the airborne spectroradiometer. The accuracy of the quantitative measurement is still under investingation, but suspended sediment concentration of less than 5 ppm can be detected. Organic and inorganic constituents can be qualitatively differentiated

FULL-DEPTH AND GRANULAR BASE COURSE DESIGN FOR PROST AREAS.

LOADS, DEFORMATION.

When properly designed and constructed, the Asphalt Institute full-depth pavement concept can be a viable design alternative for seasonal frost areas. The Corps of Engineers reduced subgrade strength frost. The the test conditions. For each design, two different thicknesses were studied in test sections placed over 12 in. of prepared subgrade and tested under light traffic conditions in Hanover, New Hampshite. After design traffic loading was exceeded, pavement failure occurred as expected in the thinner full-depth section. The thanner reduced subgrade strength section was stull in good condition after experiencing twice its design loading. Frost penetrations, pavement n-factors (surface transfer coefficients), Benkelman Beam deflections, and the spring subgrade moisture contents are also compared for the two designs

ANALYSIS (MATHEMATICS).

An approximate solution to the Neumann problem has been obtained by using the heat balance integral method. The accuracy of the solution is shown to be very good for all practical soil system cases. The thermal properties of soil systems are also expressed in terms of only the liquid volumetric fraction and combine with the approximate solution to give a rapid, accurate solution for freeze thaw problems without using graphs, tables, or transcendental equitions. A simple relation is also given for the analogous problem in cylindrical coordinates, but its range of validity is somewhat limited.

ACOUSTIC EMISSIONS DURING CREEP OF FROZEN SOILS.

Fish, A.M., et al, 1982, No.750, p.194-206, 18 refs. Sayles, F.H. 36-2402

GROUND PHYSICS, FROZEN GROUND STRENGTH, SOIL CREEP, ACOUSTICS, RHEOLOGY, STRESSES, COMPRESSIVE PROPERTIES, SOIL FREEZING, DEFORMA-

Deformation, time-dependent failure, and acoustic emissions Deformation, time-dependent failure, and acoustic emissions during unconfined compression tests of frozer Fairbanks silt were studied. Acoustic emissions (AE) are detected when the applied stress exceeds a threshold level. This threshold stress is related to the limit of long-term strength of the frozen soil. Under stress exceeding the limit of the long-term strength, the accumulation of acoustic emissions with time can be correlated with creep deformation, that is, plots of the cumulative number of acoustic pulses versus time of the cumulative number of acoustic pulses versus time have shapes similar to those of creep curves with primary, secondary, and tertiary stages. Such correspondence made it possible to describe both phenomena from the viewpoint of the unified kinetic theory of strength. Experimental data are presented, and unified constitutive equations describing deformations, time-dependent failure, and the accumulation of the acoustic emissions during short-term creep of frozen soils are derived. The time to incipient failure, when the AE rate reaches a minimum, is considered to be the most important characteristic of a creep process. It is shown that this time can be predicted theoretically if the parameters of the AE process and the stress state of the frozen soil are known.

PHASE CHANGE AROUND INSULATED BU-RIED PIPES: QUASI-STEADY METHOD. Lunardini, V.J., Sep. 1981, Vol. 103, p.201-207, 13 refs.

36-2401

FREEZE THAW TESTS, UNDERGROUND PIPE-LINES, HEAT TRANSFER, STEFAN PROBLEM, PHASE TRANSFORMATIONS, PIPELINE INSULATION, THERMAL INSULATION, ANALYSIS (MATHEMATICS).

(MATHEMATICS).

The heat transfer problem for cylinders embedded in a medium with variable thermal properties cannot be solved excatly if phase change occurs. Approximate solutions have been found using the quasi-steady method. The temperature field, phase change location, and pipe surface heat transfer can be estimated using graphs presented for parametric rangers of temperature, thermal properties, burial depth, and insulation thickness. The accuracy of the graphs increases as the Stefan number decreases and they should be of particular value for insulated hot pipes or refrigerated gas lines.

VENTING OF BUILT-UP ROOFING SYSTEMS. Tobiasson, W., Conference on Roofing Technology, 6th, Gaithersburg, MD, Apr. 30-May 1, 1981. Proceedings, 1981, p.16-21, 12 refs. 38.39RI

ROOFS, VENTILATION, THERMAL INSULA-TION, MOISTURE, DRYING, DRAINS, VAPOR BARRIERS.

BARRIERS.

Table I summarizes the information presented in this paper. The following rules of thumb are offered. I. Bituminous built-up membranes should be vented during construction to allow excess moisture to dissipate. 2. Do not rely on senting above wet-applied decks or wet-applied insulations to dry into the space below. 4. To make roofing systems less vulnerable to moisture problems avoid using moisture-sensitive materials for the bottom ply of a membrane. 5 There is no reason to vent the insulation of a roof lacking a vapor retarder. In fact, venting such roofs may do more thermal and moisture harm than good 6. When a vapor retarder is required, focus money and efforts that might be spent on vents to improving the quality of the vapor retarder. 7 Do not expect to be able to encapsulate insulation in a vapor tight, pressuriable envelope Consequently, do not worry too much about creating excess pressures within the roofing system (except within the membrane itself). 8 Do not expect to be able to dry out wet insulation in compact roofs by venting. 9 Seme drying of wet fibrous glass insulation is possible by draining away water.

FROST RESISTANCE, SOIL FREEZING, FROST HEAVE, MEASURING INSTRUMENTS, TEMPERATURE EFFECTS, TESTS.

PERATURE EFFECTS, TESTS.

The CRREL frost heave test for determining the frost susceptibility of soils and granular base materials is described. The CRREL test is conducted with a constant rate of frost penetration of 13 cm/day with water freely avaible. The frost susceptibility classification system is based on the average rate of heave for 12 days. A summary of nearly 400 tests is given to show the wide range of results for similar materials. A summary of the U.S. Army Corps of Engineers Frost Design Classification System is also given to show for what materials the frost heave test is required.

OVERVIEW OF SEASONAL SNOW METAMOR-PHISM.

Colbeck, S.C., Feb. 1982, 20(1), p.45-61, 43 refs., Presented at the U.S.-Canadian Workshop on the Properties of Snow, Snowbird, Utah, April 8-10, 1981.

SNOW PHYSICS, METAMORPHISM (SNOW), SNOW COVER STRUCTURE, SNOW WATER CONTENT.

CONTENT.
The grains in seasonal snow undergo rapid and radical transformations in sixe, shape, and cohesion. These grain characteristics affect all of the basis properties of snow. Snow is characterized as either wet or dry depending on the presence of liquid water. Wet snow is markedly different at low and high liquid contents. Dry snow is characterized as either an equilibrium form or a kinetic growth form; that is, it is either well rounded or faceted. Of course, many snow grains display either transitional features between two of these categories or features which arise from other processes. Snow is classified depending on the dominant processes of its metamorphism

SHORELINE MODIFICATION, SHORE ERO-SION, PHOTOINTERPRETATION, WATER LEV-EL, AERIAL SURVEYS, HISTORY.

EL, AERIAL SURVEYS, HISTORY.

The objectives of this investigation were to analyze past patterns of shoreline change, estimate the amounts of change in the positions of the high water line and sea cliff break and base, and estimate rates of accretion and erosion. Distances from selected reference points to the high water line, cliff break, and cliff base were measured using photonieripretation techniques on black and white 9 x 9 in serial photographs acquired in 1938, 1952, 1971 and 1974. The amounts and rates of change are calculated for the intervals between the dates of photo acquisition and for the total period from 1938 to 1974.

DRYING, VENTILATION, VAPOR BARRIERS. Nondestructive techniques are being widely used to locate wet insulation in compact roofing systems. Now that wet insulation can be found, breather vents and so-called breathable" membranes are being promoted to dry out wet insulation, thereby recovering its thermal effectiveness. Our exposure tests in New Hampshire indicate that the above ventuing methods are all rather ineffective in drying scaled specimens of perlite and fibrous glass roof insulation. It would take many decades to dry our specimens at the rates we measured over the past two years. Cross-ventilation within the insulation increased the rate of drying. For perlite insulation, the faster rate would still result in a drying time measured in decades. For fibrous glass insulation the drying time was reduced to 13 years. We have succeeded in drying fibrous glass insulation in a roof by removing the water with a vacuum cleaner.

ICE CRYSTAL STRUCTURE, ICE CRYSTAL GROWTH, GROUND ICE, SANDS, ICE AIR INTERFACE, POROSITY, WATER CONTENT, TRANSFER, MASS FLOW, EXPERIMEN-TATION.

The configuration and fabrics of ice in frozen glass beads The configuration and fabries of ice in frozen glass beads and sands with a low initial water content were observed. As suggested by Miller, the air-ice interface is convex, and pores seem to fill unstably. This produces an uneven ice distribution when the water supply is limited. Many different ice shapes and crystal distributions were observed, indicating a mixture of kinetic crystal growth processes and equilibrium constraints. Ice dendrites arose from rapid growth. Both single and multicrystalline structures were found. Clearly, a wide variety of situations is possible, depending on growth rates, nucleation sites, and local paths of heat and mass flow.

SOME FIELD STUDIES OF THE CORRELA-TION BETWEEN ELECTROMAGNETIC AND DIRECT CURRENT MEASUREMENTS GROUND RESISTIVITY.

SOIL PHYSICS. ELECTRICAL RESISTIVITY, ELECTROMAGNETIC PROSPECTING, PERMA-FROST PHYSICS, MAGNETIC SURVEYS, ELEC-TRIC FIELDS, GROUND ICE.

Electromagnetic (em) and direct-current (d-c) methods of measuring ground resistivity have been compared at permafrost and nonpermafrost sites. The em methods utilized the principles of magnetic induction and plane wave surface impedance. Layered ground models were derived from the d-c sounding data, and the theoretical values of the em methods for these models were compared with the em field results. Both em methods correlated well with the d-c data in the two cases of simple, multilayered ground of large extent. In several cases of resistive inhomogeneities, the magnetic induction data correlated well with the d-c data. In one case of a resistive inhomogeneity, the surface impedance responded well only qualitativel) and may have given some false indications of resistive substructure. It appears that in all cases where the volume of exploration was comparable, there was reasonable correlation. It is estimated that the standard data analysis procedure which assumes layering of infinite extent will apply well for the surface impedance method when disturbances in the local layering are greater than a skin depth away from the point of measurement, and for the magnetic induction method when disturbances in the layering are at a distance from the interloop axis that is greater than the interloop separation. Electromagnetic (em) and direct-current (d-c) methods of

COMPUTER APPLICATIONS.

The U.S. Army Cold Regions Research and Engineering Laboratory has recently acquired an instrumented vehicle for the measurement of forces at the tire/surface material interface. The CRREL instrumented vehicle (CIV) is equipped with moment-compensated triaxial load cells mounted in the vertical, longitudinal (in the direction of motion) and side directions. In addition, accurate wheel and vehicle speeds and rear axle torque and speed are measured. Modifications to the vehicle to facilitate the performance of traction and motion resistance tests include four lock-out type hubs to allow front, rear- or four-wheel drive and a dual brake system for front-, rear- or four-wheel braking. A minicomputer-based data acquisition system is installed in the vehicle to control data collection and for data processing, analysis, and display. Discussion of the vehicle includes its operation and use for the evaluation of the tire performance and surface material properties of motion resistance and traction. MP 1516 MP 1516

Blaisdell, G.L., et al, 1982, No.820346, International Congress and Exposition, Detroit, Michigan, Feb. 22-26, 1981, 7p., 8 refs. Harrison, W.L. 36-2756

RUBBER SNOW FRICTION, SNOW SURFACE, TRACTION, VEHICLES, ANALYSIS (MATH-EMATICS).

EMATICS). Research on vehicle mobility in snow has recently become significantly updated by the use of instrumented vehicles. Utilizing triaxial load cells in the front wheel assemblies, the vehicles are capable of measuring the traction and motion resistance forces located at the tire/snow interface. Based on these measured quantities, snow surface characterization parameters are developed. Also, using an energetics approach, a tire performance parameter is developed which offers a measure of the slip-shear energy expended by a tire moving a unit distance. This paper presents the methods, equipment and philosophy followed by the authors in evaluating tire performance in a shallow snow cover. Definitions of terms are contained in the Appendix. of terms are contained in the Appendix.

ON THE DIFFERENCES IN ABLATION SEA-SONS OF ARCTIC AND ANTARCTIC SEA ICE. Andreas, E.L., et al, Feb. 1982, 39(2), p.440-447, 41 refs.

Ackley, S.F. 36-2836

ICE MELTING, ABLATION. METEOROLOGICAL FACTORS.

Arctic sea ice is freekled with melt ponds during the ablation season. Antarctic sea ice has few, if any On the basis of a simple surface heat budget, the authors investigate the meteorological conditions necessary for the onset of surface melting in an attempt to explain these observations. The low relative humidity associated with the relatively dry winds off the continent and an effective radiation parameter winds off the continent and an effective radiation parameter smaller than that characteristic of the Arctic are primarily responsible for the absence of melt features in the Antarctic. Together these require a surface-layer air temperature above OC before Antarctic sea ice can melt. A ratio of the bulk transfer coefficients less than I also contributes to the dissimilarity in Arctic and Antarctic ablation seasons. The effects of wind speed and of the sea-ice roughness on the absolute values of bulk transfer coefficients seem to moderate regional differences, but final assessment of this hypothesis awaits better data, especially from the Antarctic (Auth.) (Auth)

SEDIMENT LOAD AND CHANNEL CHARAC-TERISTICS IN SUBARCTIC UPLAND CATCH-MENTS.

Slaughter, C.W., et al., 1981, 20(1), p.39-48, 12 refs. Collins, C.M. 36-2830

J6-28JU DISCONTINUOUS PERMAFROST, CHANNELS (WATERWAYS), GEOMORPHOLOGY, SEDI-MENT TRANSPORT, HYDROLOGY, DRAIN-AGE, SUSPENDED SEDIMENTS, WATER-SHEDS, STATISTICAL ANALYSIS

Sediment load in low-order streams of the unglaciated Yukon-Tanana Uplands of central Alaska may be related to drainage basin characteristics and to stream channel morphology. This has been investigated by analysis of selected physical hydrologi-cal and water quality data for the 104 sq km Caribou-Poker Creeks Research Watershed, 'ocated at 65 deg. 07 min N. 147 deg. 30 min W in a region of rolling to steep uplands and discontinuous permafrost. Channel morphology

data are available for first-, second- and third-order streams. Sediment load for selected points was determined over 45 weeks during summer of 1978 and 1979. Consistent differences in sediment yield, hydrologic regime and channel morphology have been determined between permafrost and non-permafrost drainages.

SLOPE.

The U.S. Army Cold Regions Research and Engineering Laboratory (USA CRREL) has long conducted research in anow, i.e., and permafrost. It also translates foreign language engin ...nng papers and publishes research reports, monographis, and bibloographies. Snow and ice roads and construction pads have been used, primarily on the Arctic Slope, during the last few winters. Some have been successful but problems exist which will require further experience and research to solve. One problem is that of snow supply. Snowfall on the Arctic Slope is limited, particularly early in the season when it is most desired. Few good data are available on total quantities and the time pattern of snowfall but Wyoming Snow Gages, now being installed by a number of government agencies and private organizations, are beginning to provide some data which can be used with some confidence. The snow which falls is often blown off by the strong winds which are common in the area so it is r x available where it is needed Research is under way on equipment and techniques for collecting snow and inducing drifting.

Peak shock pressures in frozen soal resulting from underground explosions of moderate size and their effect on fish populations are examined, based on current knowledge of shock pressure patterns and the sensitivity of fish eggs and young and adult fish to such pressures. The peak shock pressures attenuate rapidly with distance from explosion and it appears that moderate-sized explosions, such as those from standard seismic shots, can be fired within a few hundred feet of water bodies without exceeding allowable peak shock pressures in the water bodies. Experimental studies should be carred out to confirm the pattern of peak shock pressure attenuation and examine the effectiveness of shock transmission between frozen ground and the water bodies. frozen ground and the water bodies.

EMATICAL MODELS, MECHANICAL TESTS.

The acoustic emission response from fine-grained polycrystalline ice subjected to constant compressive loads was examined.

A number of tests were conducted with the nominal stress
ranging from 0 8 to 367 MPa at a temperature of -5C.

The acoustic emission response was recorded and the data
are presented with respect to time and strain. The source
of acoustic emissions in ice is considered in terms of the
formation of both microfractures and visible fractures that
develop without catastrophic faulure of the ice A model
to describe the acoustic emission response is developed.

DEFORMATION AND FAILURE OF ICE UNDER CONSTANT STRESS OR CONSTANT STRAIN-RATE.

VELOCITY, ICE STRENGTH.

The behavior of an ice dynamics model employing a viscous plastic theology is investigated. Time and space scales of the order of 3 hours and 20 km are emphasized. However, whenever possible the results are presented in a nondimensional form. Numerical parameter variations examined include the effect of the "ingid" creep rate on numerical convergence rate, the effects of ice strength on the numerical adjustment time needed to fully attain ideal plastic flow, and the effect of grid size on the behavior of simulated ice dynamics based on the results of these studies a viable numerical procedure for simulating mesoscale plastic flow is proposed.

TEMPERATURE, RIVER FLOW, ICE EDGE, AIR
TEMPERATURE, ICE MELTING.

Results are presented of a field study of the ice suppression caused by discharge of warm water at the side of the Mississippi River near Bettendorf, lowa Included in the results are measurements of lateral and longitudinal open water extents and lateral, longitudinal, and vertical water temperature profiles. Successive measurements were made on both very cold (-20C) and warm days (OC air temperature). The manner by which the ice cover extends during a change from warm to cold weather is described.

(MATIEMATICS).

Air bubbler systems are used to suppress ice formation and prevent ice damage to structures. Injection of air into the slightly more dense, warm water at the bottom of a body of fresh water raises the warm water to the surface. A bubbler system provides a simple and inexpensive means of suppressing ice if the body of water has the necessary thermal reserve. A study was conducted with a point source bubbler to examine its performance when installed under an existing layer of thick lake ice.

APPLICATION OF A NUMERICAL SEA ICE
MODEL TO THE EAST GREENLAND AREA.
Tucker, W.B., Monterey, California, Naval Postgraduate School, Dec. 1981, 109p., M.S. thesis. Refs.

SEA ICE DISTRIBUTION, DRIFT, ICE GROWTH, THERMODYNAMICS, MATHEMATICAL MOD-ELS, GREENLAND.

ELS, OREENLAND.

A dynamic-thermodynamic sea see model which employs a viscous-plastic constitutive law has been applied to the Last Greenland area. The model is run on a 40-law spatial scale at 1/4-day time steps for a 40-day period with forcing data beginning on Oct 1, 1979. Results tend to verify that the model predicts reasonable theknesses and two-locaties within the ice margin. Thermodynamic ice growth produces excessive ice extent, however, probably due to madequate parameterization of oceanic heat flux.

WEDDELL-SCOTIA SEA MARGINAL ICE ZONE OBSERVATIONS FROM SPACE, OCTO-

SEA ICE, ICE EDGE, REMOTE SENSING, ANTARCTICA WEDDELL, SEA, SCOTIA SEA.

IARCTICA WEDDELL SEA, SCOTIA SEA.

Imagery from the shuttle imaging radar-R experiment as well as other satellite and meteorological data are examined to learn more about the open sea see marpo of the Weddell-Scotia Seas region. At the see edge, the see forms into bandilate aggregates of small see flows similar to those observed in the Bering Sea. The radar backscatter characteristics of these bands suggest that their super surface is wet. Further into the pack, the radar imagery shows a transition to large from. In the open sea, large seebergs and long surface gravity waves are discernable in the radar images (Auth.)

MP 1537 ICE CRYSTAL MORPHOLOGY AND GROWTH RATES AT LOW SUPERSATURATIONS AND HIGH TEMPERATURES.

Colbeck, S.C., May 1983, 54(5), p.2677-2682, 17 refs.

ICE CRYSTAL STRUCTURE, ICE CRYSTAL GROWTH, SUPERSATURATION, TEMPERATURE EFFECTS, VAPOR DIFFUSION, DENSITY (MASS/VOLUME), MATHEMATICAL MODELS (MASS/VOLUME), MATHEMATICAL MODELS.
At an excess vapor density (supersaturation of about 1/10,000) adjacent to the ice crystal surface of 50-60 billionth g/cc, there is a transition between the highly faceted kinetic growth form and the rounded equilibrium form at temperatures above -6C. At lover temperatures there is a transition in the equilibrium form to hexagonal prisms because of a reduction in the disordered surface layer. The growth rate of ice crystals from the vapor is analyzed by a simple model which accounts for vapor flow and surface processes separately The conditions for highly temperature sensitive growth are identified from the model.

FORMATION OF ICE CRYSTALS AND DISSI-PATION OF SUPERCOOLED FOG BY ARTIFI-CIAL NUCLEATION, AND VARIATIONS OF CRYSTAL HABIT AT EARLY GROWTH STAGES. Kumai, M., Apr. 1982, 21(4), p.579-587, 14 refs.

FOG DISPERSAL, ICE CRYSTAL NUCLEI, ARTIFICIAL NUCLEATION, SUPERCOOLED FOG. MICROSTRUCTURE, ELECTRON MICROSCOPY, PLATES, ICE FORMATION, WATER VAPOR, TEMPERATURE EFFECTS.

POR, TEMPERATURE EFFECTS.

The early stages of see crystal formation in supercooled fogs were studied in detail by electron microscopy, and see nucleation experiments using liquid propone seeding were conducted in a thermostatically controlled coldroom. Ice crystals, formed by rapid cooling created by the evaporation of liquid propone from a fine nozife as temperatures from 0.1 to -40°C, were collected and replicated on filiated grids for electron microscope examinations. Most of the see crystals formed immediately after the Isquid personan seedings were spherical (although approx. 20°C were hexagonal) with diameters ranging from 0.3 to 3 micrometer and with a mean diameter of 1.5 micrometer. Electron microscopy revealed a grain boundary in some of the ice crystals.

SEA ICE, ICE STRUCTURE, PHYSICAL PROPER-TIES, CALVING, ANTARCTICA-MCMURDO SOUND.

SOUND.

This season's study of the physical and structural properties of sea ice in McMurdo Sound was restricted to sea ice that had formed since Apr. 1980 Multipear ice was observed and sampled at only one location, near Cape Chocolate on the western edge of McMurdo Sound. The locations of the sample sites are shown. The sampling program included an over-ice traverse of the bay-fast ice in McMurdo Sound. Extensive recent calving of the Koettlitz Glacier see tongue was observed in the vicinity of the Dailey Is. Preliminary investigations of the crystal structure of samples from 28 locations revealed undespread formation of congelation ice but only minimal amounts of frazil ice. Formation of a sub-ice plattlet layer with individual plates measuring up to several cm in length was observed at the majority of sampling sites. Petrographic studies revealed crystalline structures and c-axis orientations that exhibited much ta common with shore-fast ice of the arctic coast of Alaska.

SNOW ELECTRICAL PROPERTIES. SNOW DENSITY, POROSITY, SNOW CRYSTAL STRUCTURE. SNOW PHYSICS. TEMPERATURE GRADIENTS, LIQUID PHASES. WET SNOW, DIELECTRIC PROPERTIES.

DIELECTRIC PROPERTIES.

The grownerity and pocourty of dry snow varies widely expending on the history of conditions. The permittenty of dry snow mercases with mercasing ace context but it not greatly affected by the shapes of the see particles. In wer snow the permittenty mercases with logical content and the geometry is very important. However, the biquidite layer has britle effect on permittenty. The permittenty is described using Polder and van Santen's muring formulas and approximations of the geometries at high and low layed contents. It is shown that the common assumption of liquid shells over ace spheres is both physically meeting and leads to large errors.

Delaney, A.J.

DIELECTRIC PROPERTIES, ACTIVE LAYER, GROUND THAWING, PERMAFROST BASES, RADAR ECHOES.

RADAR ECHOES.
Field measurements of the dielectric constant of thawed active layers of up to 1 m in depth at four sites in Alaska have been made using short-pulse ground radar whose returns were received in the near-field radiation zone. Three sites consisted of saturated sitls with varying amounts of organic material, and the fourth site was a most sand. The reflector returning the radar signals was the active layer/permafrost interface. Analysis of the waveforms showed that all the materials were nondispersive over the radar pulse bandwidth (75-225 MHz), and this was confirmed by time domain reflectometry (TDR) studies of field samples The average dielectric constants were between 23 and 34 for the silts, which averaged between 45 and 50% water by volume, while the sandy site gave an average value of about 12 for a probable water content of about 23% by volume. These values are very smillar to the laboratory work of others and were also confirmed by TDR. The high dielectric constants of the saturated materials allowed ceurate profiling of active layer depth, and an example is presented. More detail would probably be achieved with a higher-frequency radar.

ICE FLOES, PACK ICE, FRAZIL ICE, ANTARC-TICA—WEDDELL SEA.

TICA—WEDDELL SEA.

Observations during February and March 1980 of structures in 66 separate floes in Weddell Sea pack ice show widespread occurrence of fre'il ice in amounts not previously reported in sea ice of comparable age and thickness in the Arctic. It is estimated that as much as 50% of the total ice production in the Weddell Sea is generated as frazil Average floe salinities also appear higher than those of their Arctic counterparts. Comparative studies of fast ice at 28 locations in McMurdo Sound show this ice to be composed amost entirely of congelation ice that exhibits crystalline textures and orientations that are similar to those observed in Arctic and orientations that are similar to those observed in Arctic fast ice However, avere, e fast ice salimities in McMurdo Sound are higher than those reported for Arctic fast ice of comparable age and thickness (Auth)

MP 1549 ON MODELING THE WEDDELL SEA PACK

Hibler, W.D., III, et al, 1982, Vol.3, International Symposium on Antarctic Glaciology, 3rd, Columbus, Ohio, Sep. 7-12, 1981, p.125-130, 23 refs. Ackley, S.F. 37-259

SEA ICE, PACK ICE, THERMODYNAMIC PROP-ERTIES, ICE MODELS, ANTARCTICA—WED-DELL SEA.

DELL SEA.

Some results from a dynamic-thermodynamic simulation of the seasonal cycle of the Weddell Sea pack ice are described. The model used for the study is similar to that developed for a numerical investigation of the Arctic ice cover—It employs a plastic ice rheology coupled to a two-level ice thickness distribution—The thickness characteristics evolve in response to ice dynamics, and to ice growth and decay rates dictated by surface heat calculations and by heat storage in a fixed depth oceanic boundary layer—Observed timevarying wind, temperature, and humidity fields are used together with empirical radiation fields and fixed ocean currents to drive the model. to drive the model Employing these fields, the model is integrated over two seasonal cycles Overall, the results suggest that (1) ice dynamics are essential in describing the seasonal cycle, and (2) a feedback between the atmospheric temperature and the presence of ice may be a major cause of the rapid decay of the Antarctic ice cover during the spring-summer period. (Auth. mod.)

BRINE ZONE IN THE MCMURDO ICE SHELF. ANTARCTICA.

Kovacs, A., et al, 1982, Vol.3, International Symposium on Antarctic Glaciology, 3rd, Columbus, Ohio, Sep. 7-12, 1981, p.166-171, 21 refs

A.J., Cragin, J.H. 37-266

ICE SHELVES, BRINES, MIGRATION, ANTARC-TICA-MCMURDO ICE SHELF.

Infiltration of brine into the McMurdo Ice Shelf is dominated by wave-like intrusions of sea-water triggered by periodic break-outs of the ice front. Observations of a brine step 4.4 m in height in the McMurdo Ice Shelf show that it has migrated about 1.2 km in four years. The inland boundary of the brine percolation is probably controlled largely by the depth at which brine encounters the firm/sec resulting (4.3 m). However, this boundary, is not fixed. largely by the depth at which brine encounters the firn/ice transition (43 m). However, this boundary is not fixed by permeability considerations alone, since measurable movement of brine is still occurring at the inland boundary. Freeze-fractionation of the sea-water as it migrates through the ice shelf precipitates virtually all sodium sulfate, and preferentially concomitant removal of water by freezing in the pore spaces of the infiltrated firm produces residual brines approximately seven times more concentrated than the original sea-water. (Auth. mod.)

NITRATE FLUCTUATIONS IN ANTARCTIC SNOW AND FIRM: POTENTIAL SOURCES AND MECHANISMS OF FORMATION.

Parker, B.C., et al, 1982, Vol.3, International Symposium on Antarctic Glaciology, 3rd, Columbus, Ohio, Sep. 7-12, 1981, p.243-248, 33 refs.

DEFORMATION AND FAILURE OF FROZEN SOILS AND ICE AT CONSTANT AND STEADI-LY INCREASING STRESSES.

Fish, A.M., Canadian Permafrost Conference, 4th, Calgary, Alberta, Mar. 2-6, 1981. Proceedings, Ottawa, National Research Council of Canada, 1982, p.419-428, With French summary. 16 refs.

PERMAFROST PHYSICS, FROZEN GROUND STRENGTH, FROZEN GROUND COMPRES-SIRENGIH, FROZEN GROUND COMPRES-SION, FROZEN GROUND MECHANICS, SOIL CREEP, ICE DEFORMATION, ICE STRENGTH, STRESSES, ICE CREEP, ANALYSIS (MATH-EMATICS), EXPERIMENTATION

Experimental and theoretical studies were made of the deformation and time-dependent failure of ice. Uniaxial compression tests were performed in the laboratory at constant and sion tests were performed in the laboratory at constant and steadily increasing stresses. Strength criteria and unified constitutive equations describing all three stages of creep at con.lant stress are presented. It is shown that regardless of the stress regime (constant stress or step loading) the equations describe deformation and time-dependent failure by five parameters. The form of the constitutive equations, which can be applied also to describe the mechanical properties of frozen and unfrozen soils, make it possible to obtain analytical solutions of the practical problems and to determine the creep parameters of frozen and unfrozen soils and ice in situ.

THEORY OF THERMAL CONTROL AND PRE-VENTION OF ICE IN RIVERS AND LAKES. Ashton, G.D., 1982, Vol.13, p.131-185, 38 refs. 37-684

37-684
ICE CONTROL, RIVER ICE, LAKE ICE, THERMAL REGIME, HEAT TRANSFER, WATER FLOW, WATER TEMPERATURE, BUBBLING, ICE FORMATION, ICE GROWTH, ICE MELT-ING, ANALYSIS (MATHEMATICS).

ING, ANALYSIS (MATHEMATICS).

The thermal control of ice in rivers and lakes is accomplished in most cases by modifying the energy budget of the ice cover. In most cases the modification is to increase the flow of heat to the underside of the ice cover, either by directing against it a flow of warm water obtained from other parts of the water body, as in the case of air bubbler systems, or by increasing the temperature of the existing flow of water, as in the case of rivers.

IN-SITU MEASUREMENTS OF THE ME-CHANICAL PROPERTIES OF ICE.

Tatinclaux, J.C., International Conference on Marine Research, Ship Technology and Ocean Engineering, Hamburg, Sep. 29-30, 1982. Proceedings. Inter-maritec '82, Hamburg, 1982, p.326-334, 7 refs.

ICE MECHANICS, ICE COVER STRENGTH, ICE ELASTICITY, FLEXURAL STRENGTH, FLOAT-ING ICE, ANALYSIS (MATHEMATICS).

Two methor's for in-situ determination of the bending strength and elastic modulus of ice are presented. The first method requires failure tests of a series of cantilever beams of various requires failure tests of a series of cantilever beams of various length over thickness ratios, while the second method is based on failure testing of a free-floating beam of length at least three times the ice characteristic length. Both methods avoid the need for measuring beam deflection in order to determine the elastic modulus. The analytical background of the methods is presented, and their advantages and disadvantages as compared to conventional methods are discussed together with their likely application to field or laboratory was sent as the second methods.

MP 1556 STANDARDIZED TESTING METHODS FOR MEASURING MECHANICAL PROPERTIES OF

Schwarz, J., et al, July 1981, 4(3), p.245-254, 18 refs. Frederking, R., Gavrilo, V.P., Petrov, I.G., Hirayama, K., Mellor, M., Tryde, P., Vaudrey, K.D.

ICE MECHANICS, COMPRESSIVE PROPER-TIES, TENSILE PROPERTIES, ICE ELASTICITY, STANDARDS, LOADS (FORCES), TESTS.

STANDARDS, LOADS (FORCES), TESTS.

The results of nominally similar tests vary greatly due to the fact that almost every ice research group uses different testing methods. This is of course a hindrance to the Ice Engineering field. In order to improve the quality, comparability and usefulness of the test data resulting from mechanical property investigations, the IAHR Section on Ice Problems considers it necessary to standardize ice testing methods. Herewith the Working Group of the IAHR Section on Ice Problems proposes its recommendation for "Standardized Testing Methods for Measuring Mechanical Properties of Ice." It should be noted that the suggested recommendations remain open to revision as the development of ice testing methods progresses

MP 1557 FROST SUSCEPTIBILITY OF SOIL; REVIEW OF INDEX TESTS.

Chamberlain, E.J., Aug. 1982, FHWA/RD-82/081, 110p., Refs p.83-88. 37-973

FROST HEAVE, SOIL MECHANICS, SOIL FREEZING, ICE WATER INTERFACE, ICE SOLID INTERFACE, TESTS, CLASSIFICATIONS, TEMPERATURE GRADIENTS, SOIL WATER, PARTICLE SIZE DISTRIBUTION, GRAIN SIZE.

Methods of determining the frost susceptibility of soils are identified and presented in this report. More than one Methods of determining the frost susceptibility of soils are identified and presented in this report. More than one hundred criteria were found, the most common based on particle size characteristics. These particle size criteria are frequently augmented by information such as grain size distribution, uniformity coefficients and Atterberg limits. Information on permeability, mineralogy and soil classification has also been used. More complex methods requiring pore size distribution, mosture-tension, hydraulic-conductivity, heave-stress, and frost-heave tests have also been proposed. However, none has proven to be the universal test for determining the frost susceptibility of soils. Based on this survey, four methods are proposed for further study. They are the U.S. Army Corps of Engineers Frost Susceptibility Classification System, the moisture-tension hydraulic-conductivity test, a new frost-heave test, and the CBR-after-thaw test.

DESIGNING WITH WOOD FOR A LIGHT-WEIGHT AIR-TRANSPORTABLE ARCTIC SHELTER: HOW THE MATERIALS WERE TESTED AND CHOSEN FOR DESIGN.

Flanders, S.N., et al, Structural use of wood in adverse environments. Edited by R.W. Meyer and R.M. Kel-logs. New York, Van Nostrand Reinhold Co., 1982, p.385-397.

Tobiasson, W.

37-1030 PORTABLE SHELTERS, WOODEN STRUCTURES, MILITARY TRANSPORTATION, COLD WEATHER TESTS, LCADS (FORCES), AIRPLANES, DESIGN, CONSTRUCTION MATERIANES, DESIGN, CONSTRUCTION M ALS

ALS.

Construction of a prototype shelter particularly suited to accommodate a party of four to six in the extreme cold at remote locations has been completed recently. To facultate transportation, the shelter doubles as an ISO shipping container and self-loads onto military aircraft. These modes endure severe loads. Wood was chosen as a suitable material for use in the cold. The requirement for light weight necessitated that the wood be used close to its strength limits. The limits for bonding wood and employing composite panels were tested and compared with calculated values Urethane-based adhesive was chosen to bound high-density overlay (HDO) plywood and redwood sections together. Fiberglass-reinforced plastic (FRP) mat was chosen as a material to strengthen webs against shear

SNOW MELTING, SNOW PERMEABILITY, MELTWATER, SNOW DENSITY, SNOW COVER, SATURATION, RUNOFF.

Data from snow lysimeters in California and Vermont are used to find the saturated permeability of a melting snow cover in the range of 10-40x10/(10 sq m) depending on snow density. The unsaturated permeability increases as

about the third power of liquid saturation. The gravity flow theory is shown to be an accurate representation of meltwater drainage from snow covers in .wo diverse areas even though the snow covers are treated as homogeneous units. The variation of saturated permeability with snow density occurs about as predicted by Shimizu's formula for dry snow, although ice layers decrease the permeability somewhat.

Guymon, G.L., Berg, R.L. 37-1329 FROST HEAVE, SOII VE, SOIL FREEZING, HEAT MATHEMATICAL MODELS. TRANSFER. ANALYSIS (MATHEMATICS).

ANALYSIS (MATHEMATICS).

A unifying numerical method is developed for solution of frost heave in a vertical freezing column of soil. Within one general computer code a single unifying parameter can be preselected to employ the commonly used Galerkin finite elements, subdomain weighted residual, or finite difference methods as well as several other methods developed from the Alternation Theorem. Comparing results from the various numerical techniques in the computation of frost heave to measured frost heave in a laboratory column indicates there is little advantage of the numerical technique over another.

MP 1568 DETERMINATION DETERMINATION OF THE FLEXURAL STRENGTH AND ELASTIC MODULUS OF ICE FROM IN SITU CANTILEVER BEAM TESTS. Tatinclaux, J.C., et al, Aug. 1982, 6(1), p.37-47, 4 refs. Hirayama, K. 37-1333

(MATHEMATICS).

From the theory of cantilever beams on an elastic foundation, it is shown that the strength index and modulus index of ice can be determined from measurements of either the failure load or the tip deflection, or both, of in situ cantilever beams tested over a wide enough range of ratio of beam length to beam thickness. Four methods are proposed, two of which do not require the measurement of beam deflection during beam loading, an often difficult task to perform with sufficient reliability, especially in the field

ELS.

For determining the characteristic length of a floating ice sheet, a vertical load is applied to the ice sheet either by placing dead weights in discrete increments or with a screw drive apparatus in series with a load cell, and the deflection of the ice sheet is monitored at the point of loading or near it. For a model ice sheet exhibiting loading or near it

For a model ice sheet exhibiting creep behavior, the experimental results with the screw apparatus show that the slope of the load-deflection curve decreaxes as the load increases, and one is not able to choose a unique value of the slope for the computation of characteristic length

This is attributed to relaxation of stress in ice.

FIRN QUAKE (A RARE AND POORLY EX-PLAINED PHENOMENON).

37-2018 CHANNELS (WATERWAYS), WATER FLOW, ICE COVER EFFECT, FLOATING ICE, FLOW RATE, RIVER FLOW, COMPUTER PROGRAMS. RATE, RIVER FLOW, COMPUTER PROGRAMS. HEC-2, the widely known open channel flow water surface profile computer program developed by the U.S. Army Corps of Engineers: Hydrologic Engineering Center, has been recently updated for the U.S. Army Cold Regions Research and Engineering Laboratory to account for the presence of a floating ice cover. It has been shown by many writers that at uniform flow the normal flow depth can be increased by as much as 30% by a floating ice cover. HEC-2 with the ice cover option will allow the Corps of Engineers and other users of the program to evaluate effectively the effect of an ice cover on the flow depth, flow velocity, unit discharge, etc., in a river system. This paper presents an overview of the modifications to the uniform flow equation, the required input data, and an analysis.

SOURCE MECHANISM OF VOLCANIC TREM-OR.

Qamar, A., St. Lawrence, W.F.

EARTHQUAKES, VOLCANOES, FLUID DY-NAMICS, FLUID FLOW, UNITED STATES— OREGON—HOOD, MOUNT.

Low-frequency (<10 Hz) solcanic earthquakes originate at a wide range of depths and occur before, during, and after magmatic cruptions. The characteristics of these earthquakes suggest that they are not typical tectonic events. Physically analogous processes occur in hydraulic fracturing of rock formations, low-frequency icequakes in temperate

glaciers, and autoresonance in hydroelectric power stations. We propose that unsteady fluid flow in volcanic conduits is the common source mechanism of low-frequency volcanic carthquakes (tremor). The fluid dynamic source mechanism explains low-frequency earthquakes of arbitrary duration, magnitude, and depth of origin, as unsteady flow is independent of physical properties of the fluid and conduit. Fluid transients occur in both low-viscosity gases and high-viscosity liquids. A fluid transient analysis can be formulated as generally as is warranted by knowledge of the composition and physical properties of the fluid, material properties, geometry and roughness of the conduit, and boundary conditions. Walsh, J.E.

37-2362 SEA ICE DISTRIBUTION, PERIODIC VARIA-TIONS, ICE MODELS.

Some results from a series of three-year aperiodic simulations of the Northern Hemisphere sea ice cover are reported. The simulations employ the dynamic-thermodynamic sea ice model developed by Hibber (1979) and use a one-day timestep on a 35 x 31 grid with a resolution of 222 km. Atmospheric data from the years 1973-75 are used to drive the simulations. The simulations yield as according to the control of the simulations will a seasonal cycle with executive amounts. data from the years 1973-75 are used to drive the simulations. The simulations yield a seasonal cycle with excessive amounts of ice in the North Atlantic during winter and with somewhat excessive amounts of open water in the central Arctic during summer. Despite the seasonal bias, the simulated and observed interannual fluctuations are similar in magnitude and are positively correlated. The correlations with observed data are noticeably smaller when dynamical processes are omitted from the model. The simulated outflow of ice through the Greenland-Spitsbergen passage undergoes large fluctuations both seasonally and on an interannual basis. The outflow correlates highly with the simulated fluctuations of ice coverage in the North Atlantic sector and positively with the observed fluctuations of ice coverage in the same sector.

ADHESION OF ICE TO POLYMERS AND OTHER SURFACES.

ICE ADHESION, ICE SOLID INTERFACE, ICE STRENGTH, POLYMERS, PROTECTIVE COAT-

A set of simple experiments indicated that water drops A set of simple experiments indicated that water drops can penetrate through a grease layer and make "real" contact with the substrate, then spread over the surface, depending on the surface energy of the substrate, increasing the "real" contact rea. Furthermore the ice/substrate bond is stronger than ice itself. The complex problem of ice adhesion y be explainable by combination of these findings in that the "real" contact area multiplied by the strength of ice within the area constitute the apparent adhesive strength. Conceivable effects of various factors are discussed

CRACKING (FRACTURING), TIME FACTOR.

This work examines the effect of the rate of stress application on the creep behavior of polycrystalline ice. Stress rates from 1/1000 to 1 84 MPa/s were used to achieve a creep stress of 36 MPa at test temperatures of -5 to -10C. The treatment emphasizes the effect of stress application rate on primary creep behavior and the accompanying microfracturing activity. Acoustic emission measurements taken in all tests indicate the onset and rate peak of the microfracturing activity.

FREEZING OF SEMI-INFINITE MEDIUM WITH INITIAL TEMPERATURE GRADIENT.

Lunardini, V.J., International Offshore Mechanics and Arctic Engineering Symposium, 2nd, Houston, Texas, Jan. 30-Feb. 3, 1983. Proceedings. Edited by J.S. Chung and V.J. Lunardini, New York, N.Y., American Society of Mechanical Engineers, 1983, p.649-652, 11 refs.

37-2397 SOIL FREEZING, HEAT TRANSFER, TEMPER-ATURE GRADIENTS, STEFAN PROBLEM, GEOTHERMY, HEAT BALANCE, ANALYSIS (MATHEMATICS), THERMAL CONDUCTIVITY. (MATHEMATICS), THERMAL CONDUCTIVITY.

Exact solutions to problems of conductive heat transfer with solidification are rare due to the non-linearity of the equations. The heat balance integral technique is used to obtain an approximate solution to the freezing of a semi-infinite region with a linear, initial temperature distribution. The results indicate that the constant temperature Neumann solution is acceptable for soil systems with a geothermal gradient unless extremely long freezing times are considered. The heat balance integral will yield good solutions, with simple numerical work, even for non-constant initial temperatures. MP 1584

MODELS, ENTHALPY.

An algorithm has been developed for two-dimensional freezing and thawing problems, which may also be useful for some other phase change problems. It is designed to be implemented simply in standard finite element heat conduction computer codes which use linear interpolation within elements. Substances with discrete phase change temperatures such as water suffer a step change in enthalpy across a phase change isotherm, and hence feature a theoremaily infinite heat capacity there. The algorithm handles this potentially troublesome phenomenon in a natural way through usual finite element procedures, using simple closed form expressions.

WEDDELL SEA.

The simulations employ a dynamic thermodynamic model developed in 1979 and use a 1-day time step on an 18 x 15 grid with a resolution of 122 km. Daily atmospheric data from 1979 are used to drive the simulations, which yield a seasonal cycle of ice with maximum extents close to that observed. The advance of the ice is primarily thermodynamic in nature, while the rapid decay depends critically on the presence of both leads and lateral ice advection. The average fraction of open water is substantial and varies from 10% in September to 35% in March. These values are in general agreement with estimates from satellite microwave data. Mean ice thicknesses are consistent with observations and vary from about 3 m in the perennial ice in the western Weddell to 1 m in first-year ice in the eastern Weddell. Simulated ice drift results yield mean drift rates of about 5 km/day, in good agreement with buoy drift observations with slightly inadequate northward transport in the western Weddell. Near the ice edge the drift rates are relatively insensitive to the ice strength Near the coast, however, lower strengths are found to yield a decrease in northward drift rates. (Auth. mod.)

TRANSPORT OF WATER IN FROZEN SOIL. EFFECTS OF ICE ON THE TRANSPORT OF WATER UNDER ISOTHERMAL CONDITIONS. Nakano, Y., et al, Mar. 1983, 6(1), p.15-26, 16 refs. Tree, A.R., Oliphant, J.L., Jenkins, T F 37-3558

SOIL WATER MIGRATION, FROZEN GROUND PHYSICS, GROUND ICE, SOIL FREEZING, WATER TRANSPORT, TEMPERATURE EFFECTS, ANALYSIS (MATHEMATICS).

Effects of ice on the transport of water in frozen soil were investigated under isothermal conditions. Based on the experimental results obtained using a marine-deposited clay at 10°C, the presence of ice is shown to significantly affect the transport of water under centain circumstances. A theoretical analysis of the experimental results and a discussion of a possible mechanism for water transport in frozen soil are presented.

SEA ICE, ICE COMPOSITION, ICE STRUCTURE, ALGAE, WEDDELL SEA.

ALGAE, WEDDELL SEA.

Twenty of 27 ice cores and 13 surface ice samples taken between 59 deg 21 min S and 62 deg S have been analyzed for ice structure, salinity, nutrients, fluorescence, chlorophyll a, phaeo-pigment, diatom species enumeration, and bacteria. The primary physical feature is the dominance of frazil ice structure as opposed to congelation ice. The salinity range is 2.4 to 13.7% with the higher salinities within the upper 15 cm. Chemical analysis of nutrients in the cores indicates that they do not follow a dilution curve Silicate, phosphate, and nitrate are found in higher concentrations in the adjacent surface than in the ice cores. Natrite levels, however, are two to five times higher in the surface layer of the ice cores than in the adjacent surface water Chlorophyll a followed a pattern similar to that of nitrite. Phaeo-pigment ranged from 0.04 to 4.02 mg/cu m Meltwater fluorescence appears to scale with salinity. Diatoms are present at all sample levels in the ice cores, but in varying concentration and condition. Active growth occurs varying concentration and condition.
in the surface layers. Active growth occurs MP 1610

SUPERCOOLED FOG. FOG DISPERSAL WEATHER MODIFICATION, ICE FORMATION, COMPRESSED AIR.

Experiments have been performed under controlled and free environment conditions to determine the technical feasibility of using the cooling resulting from the adiabatic expansion of compressed air to initiate ice crystal production in a

supercooled fog. These experiments have shown that for most supercooled temperatures, approximately 1000 cc of air when compressed to 60 paig and released through a supersonic nozzle will produce the same number of ice crystals as does the evaporation of 1 cc of liquid propane. It is estimated that a compressed air supercooled fog dispersal system would consume approximately 6% of the hydrocarbon fuel presently consumed by operational systems using liquid propane. propane spray.

SEA ICE, ICE ELECTRICAL PROPERTIES, ANISOTROPY, ICE CRYSTAL STRUCTURE, ELECTROMAGNETIC PROPERTIES, OCEAN CURRENTS, REMOTE SENSING.

Results of impulse radar studies of sea ice near Prudhoe Bay. Alaska, show that where there is a preferred current direction under the ice cover the crystal structure of the ice becomes highly ordered. This includes a crystal structure

with a preferred horizontal coaxis that is oriented parallel with a preferred horizontal c-axis that is oriented parallel with the local current. The radar studies show that this structure behaves as an anisotropic dielectric. The result is that when electromagnetic energy is radiated from a dipole antenna in which the E-field is oriented perpendicular with the c-axis azimuth, no bottom reflection is detected. It was also found that the frequency dispersion of anisotropic sea ice varies in the horizontal plane and is related to the average bulk brine volume of the ice. The bulk delectric constant of the ice, as determined from impulse travel time, shows little correlation with the coefficient of anisotropy.

Results of extensive studies of earth resistivities of low tempera Results of extensive studies of earth resistivities of low temperature soils are presented. Ground measurements of the electromagnetic field components of radio waves propagated at low frequencies from distant transmitters and of the inductive coupling between two loop antennas are described. Results of measurements by these methods are compared with each other and with actual findings from excavations and borings at permafrost sites. The measurements are shown to provide data on locations of lens ice, indicate zones of thawing, give indications which permit estimating resistivities of layers and permit construction of a map of Alayka identifying major resistivity zones. Airborne evaluation of remotely propagated waves permits construction of resistivity contour maps. Reasons for variations in resistivity among various categories of frozen soils are discussed.

MODELS.

Due to the nonlinear nature of the ice interaction, seasce build-up against coasts and structures is a complex process.

This build-up significantly affects mesoscale (10 to 100 km)
ice motions over typical forecast time scales of several days.

To examine the ramifications of assuming a non-linear ice
interaction in ice forecast models, we have carried out a
series of idealized simulations employing a viscous plastic
sea-ice rheology. These simulations employ constant wind
fields at a gnd resolution of 18.5 km and allow the ice
to build up and strengthen

With the plastic ice interaction
the ice build-up is found to take place by means of a
ridging front Depending on the nature of the strengththickness coupling, this build-up is accompanied by kinematic
wave propagation effects.

EXPERIMENTAL DETERMINATION OF THE BUCKLING LOADS OF FLOATING ICE

PROTECTIVE COATINGS, ICE CONTROL, ICE PREVENTION, ICING, SHEAR STRENGTH, ICE STRENGTH, SURFACE PROPERTIES, ICE ADHESION, COUNTERMEASURES, TESTS.

ADHESION, COUNTERMEASURES, TESTS.

Much effort over many years has gone into the search
for an effective, durable, eavily applied and incepensive material
to eliminate the force of adhesion between the and a substrate.
The objective of zero the adhesion on an unheated surface
which would either prevent the formation of the or ensure
self-shedding of very thin accretions has not yet been achieved.
Many commercially available coatings do succeed in reducing
the force of adhesion below 15 psi (1034 kPa) and survive
at least five freeze release cycles, two arbitrarily established
criteria. Laposure for rain crossion, however, increases the
force of adhesion beyond this value for most materials.

As part of a continuing project at CRRLL, a test procedure
for measuring the shear strength of rice at failure has been
developed and a large number of candidate materials have
been tested.

WIND VELOCITY, POWER LINE SUPPORTS.

Four winter field seasons of simulated power line icing data were obtained during the years 1977-1981.

Measurements were obtained of the icing characteristics, loads on the wire, and wind conditions simultaneously.

Loads were measured using a single-axis load cell in line with the wire during the first three seasons, and a tri-axial load cell (resolving three perpendicular force components) in the 1980-81 winter season.

Winds were measured using a vaned pitot-static tube located near one end of the wire

MEASUREMENT OF ICE FORCES ON STRUC-TURES.

Sodhi, D.S., et al, Design for ice forces. Edited by S.R. Caldwell and R.D. Crissman, New York, N.Y., American Society of Civil Engineers, 1983, p.139-155.

Haynes, F.D.

Jo-399 ICE LOADS, ICE PRESSURE, OFFSHORE STRUCTURES. IMPACT STRENGTH, ICE STRENGTH, RIVER ICE, LAKE ICE, ICE ME-CHANICS, STRAINS, TIME FACTOR, MEASUR-ING INSTRUMENTS.

Methodologies and techniques are discussed for measuring ice forces on fixed structures situated in rivers and lakes. The usual method of measuring ice forces is to place a load frame between the moving ice and the structure and to measure the reactive forces with load cells or strain gages. Another method is to measure the acceleration, displacement or strain at a few points on the test structure and relate the measurements to ice forces. The size and anu relate the measurements to ice forces. The size and shape of the force measuring system depend upon the mode of ice failure, the distribution of the ice forces and the logistics associated with each site. The variations of ice force with respect to time are generally very high during crushing and impact, and the response of the force-measuring system should be sufficiently fast.

METHODS OF ICE CONTROL

ICE LOADS, STRUCTURES, ICE PRESSURE, ICE SOLID INTERFACE, EXPERIMENTATION, PIPES (TUBES).

PIPES (TUBES).

Ice action on two cylindrical structures, located side by side, has been investigated in a small-scale experimental study to determine the interference effects on the ice forces generated during ice structure interaction. The proximity of the two structures changes the mode of ice failure, the magnitude and direction of ice forces on the individual structure, and the dominant frequency of ice force variations. Interference effects were determined by comparing the experimental results of tests at different structure spacings.

ICE JAMS IN SHALLOW RIVERS WITH FLOODPLAIN FLOW.

Calkins, D.J., Sep. 1983, 10(3), p.538-548, 14 refs.

ICE JAMS, RIVER ICE, RIVER FLOW, ICE CON-DITIONS, ICE COVER THICKNESS, FLOATING ICE, HYDRAULICS, FLOODS, PLAINS, COMPUTER APPLICATIONS.

PUTER APPLICATIONS.

The equilibrium ice jam thickness given by Pariset et al, is modified to yield a clearer, consistent relationship between the flow hydraulics and thickness in the modified equations are analyzed with respect to a floating ice jam in the main channel with flow also occurring in the floodplain. The final derivation allows the expected ice jam thickness to be computed, given the bed and ice cover thickness. The analytical computation for the ice jam thicknesses is compared with prototype data on ice jam thincknesses from four shallow rivers which had significant floodplain flow with the ice jam event.

ASYMMETRIC PLANE FLOW WITH APPLICA-TION TO ICE JAMS.

Gögüs, M. 38-1629

ICE JAMS, WATER FLOW, FLOW RATE, SHEAR STRESS, FRICTION, SURFACE ROUGHNESS, VELOCITY, ANALYSIS (MATHEMATICS), TURBULENT FLOW.

An available turbulence method is used to prove that in plane flows between two boundaries with asymmetric roughness the plane of maximum velocity is not the plane of zero shear stress. By dividing the flow at the plane of zero shear stress, laboratory and field data on flows below simulated shear stress, laboratory and field data on flows below simulated and actual ice jams are analyzed to derive equations for the boundaries friction factors in terms of mean flow velocity, depth of flow zone, and boundary roughness for smooth and fully rough boundaries. These equations are applied to the calculations of ice jam characteristics. For the jams studied, the present method gives a variation of about 10% in the jam characteristics with a method based on dividing the flow at the plane of maximum velocity.

(MATHEMATICS).

A system has been developed by the U.S. Army Cold Regions Research and Engineering Laboratory to measure the mass concentration of falling snow crystals. It is known as ASCME (Airborne Snow Concentration Measuring Equipment) and is described in this paper. ASCME's general performance has been evaluated based on concurrent measurements of precipitation rate. A strong correlation between airborne-snow mass concentration and precipitation rate yields an estimate of particle fall velocity close to that observed by other researchers. Factors affecting system accuracy have been investigated and are discussed. Examples are given of the utilization of ASCME data in analyses of electromagnetic energy propagation in falling snow. PROPAGATION, FREEZE THAW CYCLES.
Providing ground truth for the backscatter and absorption effects of a snow cover on electromagnetic waves has long been a problem One characteristic of the snow cover which has been particularly difficult to measure is its free, or liquid, water content—the fraction of the snow's volume which exists in the liquid state. Five methods which have been used for measuring this parameter are described and their merits and deficiencies are discussed. Two of the methods are calorimetric, measuring the free water content as a function of the heat added to or removed from a snow sample while completely melting or freezing it. The third uses the freezing point depression observed on adding a salt solution to a snow sample to calculate the snow's free water content. In the fourth procedure, a snow sample is completely dissolved in ethyl or methyl alcohol The corresponding decrease in temperature is inversely related to the free water content of the snow The final technique is electronic above a certain frequency, the electrical capacitance of snow is related to its density and free water content. With accurate calibration, devices which measure snow capacitance are likely to be the simplest and fastest means of providing free water measurements (Auth.)

COMMENTS ON THE METAMORPHISM OF SNOW.

Colbeck, S.C., 1983, Vol.414, p 149-151.

METAMORPHISM (SNOW), SNOWFALL, SNOW CRYSTAL GROWTH, GRAIN SIZE, TEMPERATURE GRADIENTS, CLIMATIC FACTORS, WET SNOW.

Snow precipitation takes a variety of forms depending on the conditions in the atmosphere at the time of the snowfall. Regardless of what particular conditions prevail at that time, once the snow particles reach the ground they immediately begin changing. This is not surprising since the snow cover is at or close to its melting temperature, has a very large specific surface area, and has ever changing boundary conditions. They snow and dry snow are very different. They have different properties and even looked different. They have different properties and even looked they because they snowfall followed some time later by melting is the normal sequence of events. (Auth.) MP 1651 MP 1651

CONTENT, TOPOGRAPHIC SURVEYS, LANDSAT, CLOUD COVER, MAPPING.

SAT, CLOUD COVER, MAPPING.

The TM aboard Landsat-4 launched on July 16, 1982, represents a major advance in Earth resources sensors. Its seven spectral bands record surface radiation in blue, green, red, near infrared, middle infrared and thermal wavelengths. The spatial resolution of approximately 30 meters represents a sevenfold increase over the previous Landsat sensor, the multispectral scanner subsystem (MSS). In addition, TM has greater radiometric sensitivity, distinguishing 256 quantization levels, compared with 64 for the MSS. These potential improvements have significant implications for satellite remote sensing in cold environments. The addition of the middle infrared bands will permit clouds to be distinguished from snow. It may also be possible to relate spectral response in this range to snow condition and hence water content. The thermal band responds to differences in surface temperature, which may be related to variations in soil moisture and drainage. These are important considerations for cold region construction. TIVE COATINGS, TESTS.

During the fall of 1981 and the spring of 1982, eight test items were established on an asphalt pavement in Fairbanks, Alaska. The test items were two sections of untreated pavement, yellow-painted pavement, white-painted pavement, "standard" chip seal, fine-grained "standard" chip seal, chip seal with dark brown aggregate, and chip seal with white marble aggregate. The test items were located on a main road. Surface temperatures were monitored hourly by thermocouples attached to an automatic data collection system. The ambient air temperature, wind suced and direction, amount thermocouples attached to an automatic data collection system. The ambient air temperature, wind speed and direction, amount of precipitation, and radiation balance were continuously recorded at an untrafficked pavement approximately 100 m from the test items. Incident and reflected shortwave radiation measurements were made nearly every week-lay over each test item using a hand-held radiometer. Neatcors, ratios of surface thawing indexes to air thawing indexes varied from about 1.2-1 3 for the white- and yellow-painted surfaces, respectively, to about 1.4-1 5 for the other surfaces.

EVAPOTRANSPIRATION.
Precipitation-runoff ratios were measured on Glenn Creek, a small, second-order, subarctic stream located near Fairbanks, Alaska, in the Yukon, Tanana Upland physiographic province Glenn Creek drains a watershed of 2.25 sq km, of which 70% is underlain by permafrost. A Parshall flume was used to measure streamflow, and a pair of 1.22 m by 2.44 m lysimeters were used to measure precipitation and runoff from the moss-covered permafrost slope. The data from one summer season (1979) and one snowmelt season (1980) indicate the sloping surfaces of the watershed have a very fast response time, long recession, and subsurface runoff prior to complete saturation of the overlying organic material Glenn Creek streamflow is comparable to the lysimeter runoff with regard to response time and runoff recession, however the watershed precipitation-runoff ratio is much lower. This is attributed to longer travel distances in the watershed, which result in greater evaportanspiration losses, little contribuwhich result in greater evapotranspiration losses, little contribu-tion from the non-permafrost areas, and only partial areas of the watershed contributing to the streamflow.

MP 1655 FROST HEAVE OF SALINE SOILS.

Chamberlain, E.J., International Conference on Permafrost, 4th, Fairbanks, Alaska, July 17-22, 1983. Proceedings, Washington, D.C., National Academy Press, 1983, p.121-126, 8 refs. 38-1121

SALINE SOILS, FROST HEAVE, SOIL CHEMISTRY, SOIL FREEZING, ICE LENSES, BRINES, SHEAR STRESS, TESTS.
Theories of ice segregation and frost heave processes in saline soils are briefly examined and modified to explain observations made on clay and sand soils frozen under laboratory conditions. Seawater was observed to reduce the rate of frost heave by more than 50% for both soil types and to dramatically reduce the size of ice lenses. The effect of seawater is to cause the formation of a thick active freezing zone with many ice lens growth sites, each with its own brine concentration. Unbounded brine-rich soil zones between ice lenses are identified as potential zones of low shear strength

MP 1656 LONG-TERM ACTIVE LAYER EFFECTS OF CRUDE OIL SPILLED IN INTERIOR ALASKA. Collins, C.M., International Conference on Permafrost, 4th, Fairbanks, Alaska, July 17-22, 1983. Proceedings, Washington, D.C., National Academy Press, 1983, p 175-179, 19 refs.

OIL SPILLS, ACTIVE LAYER, ENVIRONMENTAL IMPACT, THAW DEPTH, ALBEDO, SEASONAL VARIATIONS, TEMPERATURE EFFECTS, UNITED STATES—ALASKA.

Two experimental oil spills of 7570 liters each were conducted at a black-spruce-forested site in February and July of 1976. The long-term effects of the spills on the active layer were directly related to the method of oil movement. The winter spill moved beneath the snow, within the surface moss layer, and the summer spill moved primarily below the moss, in the organic soil. The summer spill affected an area rearly one and one-half times that of the winter spill. Only 10% of the 303 sq m summer spill area and one-half times that of the winter spill area increased from 1977 to 1980 average thaw depth was 72 cm ss. 48 cm in the control and remained essentially the same in 1981 and 1982. Thaw depths in the winter spill area continued to increase until 1982 to an average of 92 cm. Summer temperatures 5 cm under the blackened surface. Presumably the change in albedo due to the surface oil accounts for the increased thaw in the winter spill area. Two experimental oil spills of 7570 liters each were conducted

MODELS, ICE LENSES, ICE MELTING.

A one-dimensional mathematical model of frost heave based upon a nodal domain integration analog is compared to data collected from a Winchendon, Mass., field site. Air and soil temperatures, pore water pressures, and groundwater level data were collected on test sections containing six different soils during the winters of 1978-1979 and 1979-1980. The soil samples were evaluated in the laboratory to determine soil moisture characteristics, hydraulic conductivity as a function of pore water tensions, density, and other parameters. The parameters were used together with assumed thermal parameters in a one-dimensional model that calculates the distributions of temperature and moisture content as well as the amount of ice segregation (vertically lumped as well as the amount of ice segregation (vertically lumped frost heave) and thaw consolidation. Using measured air and soil surface temperatures as input data, the simulated frost heave and thaw consolidation agreed well with measured ground surface displacements that resulted from ice segregation ice lens melting.

MP 1658 RELATIONSHIPS BETWEEN ESTIMATED MEAN ANNUAL AIR AND PERMAFROST TEM-PERATURES IN NORTH-CENTRAL ALASKA.

The time- and position-dependent locations of the 0 C isotherm were calculated using two modelling strategies a domain method and a boundary integral method. Simulations were made for the runway embankment at Deadhorse Airport mear Prudhoe Bay. Alaska The same thermal properties, initial conditions, and boundary conditions were used in both models. Simusoidal surface temperature variations, dependent upon surface type and exposure, were used in the simulations rather than measured surface temperatures. The positions of the 0 C isotherm determined by the boundary integral method near the time of maximum thaw penetration were essentially the same as those determined by the finite element method, and results from both models agreed closely, within a few centimeters over a total freezing depth of about 2.5 m, with the measured positions. The largest differences between measured and computed positions occurred early in the freezing and thawing seasons. The primary advantage of using the boundary integral method for problems specifically of the type considered herein is that it requires only a few nodal points, so computer simulations

can be completed rapidly on a micro computer. If the two-dimensional thermal regime is necessary, the finite element method is most suitable

MP 1660 RECOVERY AND ACTIVE LAYER CHANGES FOLLOWING A TUNDRA FIRE IN NORTH-WESTERN ALASKA.

Johnson, L., et al, International Conference on Perma-frost, 4th, Fairbanks, Alaska, July 17-22, 1983. Pro-ceedings. Washington, D.C., National Academy Press, 1983, p.543-547.

GROUND ICE, HUMMOCKS, SOIL TEMPERATURE.

An upland tundra fire, started by lightning, burned 48 sq km near the Kokolik River in northwestern Alaska during late July and early August 1977. Permanent plots were established to monitor recovery of severely, moderately, and lightly burned areas as well as unburned tundra. During the following 5 years the original permanent plots and other portions of the burn were observed annually. Vegetative recovery was most rapid and active layer effects were least on the moist sedge-shrub tundra. Recovery was slower on a high-entered polygonal area and on severely burned tussock tundra. By August 1979 the sedge-shrub tvegetation had largely recovered while both the polygonal ground and the tussock tundra were still readily recognizable as burned areas. Accelerated hydraulic and thermal crossion had occurred on some slopes, resulting in exposures of massive bodies of ground ice. Active layer thicknesses averaged 27 cm in the unburned areas and 35 cm within severely burned areas in August 1979 and reached a maximum at all but one site in August 1979. Depth of thaw decreased between 1979 and 1982 in the sedge-shrub tundra and in the lightly burned shrub tundra and remained at the same increased level through 1982 at all other sites.

CYCLES, AERIAL SURVEYS.

The distribution and volume of ice in perennially frozen sediments beneath three unglaciated sites in northern Alaska vary with the grain size and depositional origins of the sediment, thermal history (permafrost aggradation and degradation), and age of the terrain and deposits. Substantial lateral variation in near-surface ice volume exists between and within each site, but reasonably consistent trends in ice content with depth were measured beneath individual landforms. Primary deposits, those deposited and frozen without postdepositional thermal or sedimentologic modification, contain the highest volume of ice at each locality. Sediments that have undergone thawing or resedimentation uon, contain the nignest volume of ice at each locality. Sediments that have undergone thawing or resedimentation typically contain much less excess see Thaw lake, slope, or fluvial processes modify ice contents and produce sedimentary sequences with a spatial distribution of ice determined by these depositional processes and the subsequent thermal history.

Studies have indicated a relation between subfreezing temperature in a fine-grained soil and pressure (moisture tension) in the film water adjacent to an ice lens. During the experiments reported here, concurrent measurements were obtained of temperature and pressure in the liquid water phase of a freezing silt soil. Freezing was from the top down utilizing an open system, with the water table held at the base of a specimen 30 cm long. The freezing front advanced into the specimen at a generally decreasing rate from 20 mm/day to 5 mm/day. The tests utilized a special tensiometer developed at CRREL that continues to measure moisture tension below a temperature of 0 C Studies have indicated a relation between subfreezing temperaa species tensioneter developed at CRREL that continues to measure moisture tension below a temperature of 0 C as long as continuity with the unifozen water is maintained. Moisture tensions were registered continuously up to 75 kPa (0.75 atm), after which the tension remained constant or decreased slightly.

ICE. The soil-water diffusivities of soils containing no ice were determined at -1 C by an experimental method recently introduced. The theoretical basis of the method is presented. The measured diffusivities of three kinds of soils are found to have a common feature in that the diffusivity increases with increasing water content, attains a peak, and increases again as the water content increases. This common feature of the soils at the subzero temperature is discussed in comparison with unfrozen soils. The experimental data appear to indicate that the basic transport mechanism of water in soils containing no ice at the subzero temperature is essentially the same as that in unfrozen soils containing a small amount of water.

MP 1665 SEISMIC VELOCITIES AND SUBSEA PERMA-FROST IN THE BEAUFORT SEA, ALASKA.

Neave, K.G., et al, International Conference on Perrveave, K.O., et al, International Conference on Permafrost, 4th, Fairbanks, Alaska, July 17-22, 1983. Proceedings, Washington, D.C., National Academy Press, 1983, p.894-898, 17 refs. Sellmann, P.V.

The distribution of high-velocity material was used as an indicator of ice-bonded permafrost. Observations from ice survey and marine seismic records, coupled with control from a small number of drill holes, suggest that ice-bonded permafrost is extremely widespread in the Beaufort Sea. Large areas of high-velocity material at shallow depths, 10-40 m below the seabed, were observed near Prudhoe and Harrison Bays. In some cases these zones extended up to 35 km from shore. It was also common to find that depths to the high-velocity material increased with distance from the shore. Observed depths were as great as 150-230 m below the seabed.

WATER MIGRATION DUE TO A TEMPERA-TURE GRADIENT IN FROZEN SOIL.

Oliphant, J.L., et al, International Conference on Permafrost, 4th, Fairbanks, Alaska, July 17-22, 1983. Proceedings, Washington, D.C., National Academy Press, 1983, p.951-956, 10 refs.

Closed soil columns at an initially uniform total water content were subjected to a nearly linear and constant temperature

gradient along their length. At various times, the columns were sectioned and water content as a function of position was determined gravimetrically. Unfrozen water content vs. temperature curves were also determined with a nuclear magnetic resonance technique on separate samples of the same soil at the same dry density. It was found that the water migrated from the warm to the cold end and two zones developed in each of the tubes, one that contained only liquid water and the other containing ice and water. The boundary between the two zones also migrated toward the cold end as the experiment progressed, and the water content of the zone containing only water fell while that of the zone containing ice and water increased.

SUNDANT LAYER, METEURICAL INSTRUMENTS, HEAT FLUX, ICE EDGE.

During a traverse of the Antarctic marginal ice zone (MIZ) near the Greenwich Mendian in October 1981, we launched a series of radiosondes along a 150-km track starting at the ice edge. Since the the wind was from the north, off the ocean, these radiosonde profiles showed profound modification of the atmospheric boundary layer (ABL), as the increasing surface roughness decelerated the flow. The primary manifestation of this modification was a lifting of the inversion layer with increasing distance from the ice edge by the induced vertical velocity. But there was also a cooling of the stably stratified mixed layer below the inversion and a consequent flux of sensible heat to the surface that averaged over 200 W/sq m. The magnitude of this flux suggests that atmospheric heat transport plays a significant role in the destruction of ice in the Antarctic MIZ. (Jsing the rising of the inversion and ABL similarity theory, we estimated the neutral stability drag coefficient across the MIZ increased from its open ocean value, 2012, at the ice cdge to .004 at 80-90% ice concentration. The present an equation for this dependence of drag on ice concentration that should be useful for modeling the surface stress in marginal ice zones. (Auth.)

RAPHY, ANTARCTICA—WEDDELL SEA.

The general charac , ristics and microwave radiative properties of sea ice in the Weddell Sea region during the onset of , pring are studied by using the NIMBUS 7 Scanning Multichannel Microwave Radiometer (SMMR) and other satellite sensors in conjunction with in situ observations. The position of the ice edge, the gradient of ice concentration, and the width of the Marghall lee Zone are inferred from the microwave data and are found to be consistent with ship observations especially at 18 GHz. The sensitivities of the various SMMR frequencies to surface and other effects are investigated by using multi-spectral cluster analysis. The results show considerable variability in emissivity, especially at 17 GHz, likely associated with varying degrees of surface wetness, ice concentrations are derived by using two methods: one that assumes fixed emissivities for consolidated ice and an iterative procedure that accounts for the variable emissivities to be variable gives ice concentrations that are more consistent with qualitative field observations (Auth)

POSSIBILITY OF ANOMALOUS RELAXATION DUE TO THE CHARGED DISLOCATION PROC-

ACOUSTICS, RHEOLOGY, TESTS.

This work examines the effect of the rate of stress application on the creep behavior of polycrystalline ice. Stress rates from 1/1000 to 1.84 MPa/s were used to achieve a creep stress of 3.6 MPa at test temperatures of -5 and -10C. The treatment emphasizes the effect of stress application rate on primary behavior and the accompanying microfracturing activity. Acoustic emission measurements taken in all tests indicate the onset and rate peak of the microfracturing activity. The stress application rate has little effect on the minimum strain rate, the strain at which it occurs, or the characteristics of tertiary erren provided that the the minimum strain rate, the strain at which it occurs, or the characteristics of tertiary creep provided that the loading ramp ends prior to reaching the nominal failure strain of 1.0 percent. Primary creep behavior is significantly affected only at rates below about 1/100 MPa/s Results indicate that when the loading ramp continues through the failure strain, no minimum strain rate occurs, but rather the strain rate increases monotonically thoughts the strain. the strain rate increases monotonically throughout the entire test.

TIONS, CLIMATE, ICE ACOUSTICS.

The marginal uce zones (MIZ) are regions where temperate and polar climate systems interact, resulting in strong horizontal and vertical gradients in the atmosphere and the ocean These gradients lead to mesoscale processes which affect the heat, salt, and momentum fluxes at the ice margin. It is therefore important to increase our understanding of these processes in order to model the air-ice-ocean system in the MIZ, and to build up a predictive capability of the ice margin. Parameterization of these processes is also necessary in large scale modeling of the sea ice influence on the global climate system. This paper reviews our knowledge of physical processes occurring in the marginal ice zones, points out problem areas and describes Marginal lee Zone Program (MIZEX) to be initiated in 1983

THERMAL REGIME.

The deterioration of floating ice covers is analyzed to determine under what conditions the ice cover loses strength due to internal melting. The analysis considers the interaction between sensible heat transfer and long wave radiation loss at the surface, the surface albedo, the short wave radiation penetration and absorption and the unsteady heat conduction within the ice. The thermal analysis then leads to a determination of the porosity of the ice that allows strength analysis to be made using beam-type analyses. The results provide criteria to determine when and how rapidly the ice cover loses strength and under what conditions it will regain the original strength associated with an ice cover of full integrity.

A two-dimensional model of coupled heat and moisture flow in frost-heaving soils is developed based upon well known equations of heat and moisture flow in soils. Numerical solution is by the nodal domain integration method which

includes the integrated finite difference and the Galerkin finite element methods. Solution of the phase change process is approximated by an isothermal approach and phenomenological equations are assumed for processes occurring in freezing or thawing zones. The model has been verified against experimental one-dimensional soil thawing tank data as well as two-dimensional soil seepage data. The model has been applied to several simple but useful field problems such as roadway embankment freezing and frost heaving.

Over two hundred unconfined compression tests were performed on vertical ice samples obtained from ten multi-year pressure ridges in the Beaufort Sea. The tests were performed on a closed-loop electrohydraulic testing machine at two strain rates (17100,000 and 171000/s) and two temperatures (-20 and -5C). This paper summarizes the sample preparation and testing techniques used in the investigation and presents data on the compressive strength and initial tangent modulus of the ice. Over two hundred unconfined compression tests were per-

VARIATION OF ICE STRENGTH WITHIN AND BETWEEN MULTIYEAR PRESSURE RIDGES IN THE BEAUFORT SEA.

Weeks, W.F., International Offshore Mechanics and Arctic Engineering Symposium, 3rd, New Orleans, Louisiana, Feb. 12-17, 1984. Proceedings, Vol.3. Edited by V.J. Lunardini, New York, American Society of Mechanical Engineers, 1984, p.134-139, 6 refs. 38-2036

ICE STRENGTH, PRESSURE RIDGES, COM-PRESSIVE PROPERTIES, ICE STRUCTURE, ICE COVER STRENGTH, STRAINS, TEMPERATURE EFFECTS, POROSITY, SEA ICE, BEAUFORT

SEA.

A recent series of tests on the uniaxial compressive strength of ice samples taken from multiyear pressure ridges allows the testing of several hypotheses concerning the variation in strength within and between ridges. The data set consists of 218 strength tests performed at two temperatures (-5 and -20C) and two strain rates (1'1000 and 1'100,000/s). There was no significant difference between the strength of the ice from the ridge sails and the ice from the ridge keels when tested under identical conditions. As the total porosity of the ice from the sails is higher by 40% that the ice from the keels, the lack of a significant difference is believed to result from the large variations in the structure of the ice which occur randomly throughout the cores. A is believed to result from the large variations in the structure of the ice which occur randomly throughout the cores. A three-level analysis of variance model was used to study the variations in strength between 10 different ridges, between cores located side by side in a given ridge, and between samples from the same core. In all cases the main factor contributing to the observed variance was the differences within cores. This is not surprising considering the rather extreme local variability in the structure of ice in such ridges. There was no reason at the 5% level of significance to doubt the hypothesis that the different cores at the same site and the different ridges have equal strength means

RELATIONSHIP BETWEEN CREEP AND STRENGTH BEHAVIOR OF ICE AT FAILURE. Cole, D.M., Oct. 1983, 8(2), p.189-197, 4 refs

ICE STRENGTH, ICE CREEP, ICE MECHANICS, STRESSES, STRAINS,

This work explores the correspondence between the results of creep and strength tests performed on isotrope polycrystal-incide. A unique experimental procedure, termed a two-mode test in the present work, allows the testing of a single specimen under conditions of constant deformation rate up to failure and constant load thereafter. Using this procedure, the prevailing values of stress, strain and strain rate can be compared at the failure point under the two test modes without the influence of specimen variation. The effect of the stress path prior to failure on the creep behavior after failure can also be investigated. Results indicate coincidence of the failure points from creep and strength tests in stress strain rate strain space. Further more, it appears that within the range of satishles tested, the creep behavior after the mode which at failure is independent of the stress path experienced before failure. (Auth.) This work explores the correspondence between the results

ICE STRENGTH, PRESSURE RIDGES, COM-PRESSIVE PROPERTIES, STRAIN TESTS, ICE STRUCTURE, TEMPERATURE EFFECTS, SEA ICE, LOADS (FORCES), POROSITY.

A series of 222 uniaxial constant-strain-rate compression tests were performed on vertical multi-year pressure ridge sea ice samples. A preliminary analysis of the effect of structure on the compressive strength of the ice was performed on 78 of these tests. Test parameters included a temperature of -5C (23F) and strain rates of 1 100,000 and 1/1000/s. Columnar ice loaded parallel to the elongated crystal axes and perpendicular to the crystal c-axis was consistently the strongest type of ice. The strength of the elongated crystals approached the plane of maximum shear. Samples containing granular ice or a mixture of granular and columnar ice resulted in intermediate and low strength values. No clear relationship could be established between structure and strength for these ice types. However, in general, their strength decreased with an increase in porosity A series of 222 uniaxial constant-strain-rate compress

MP 1686 INFLUENCE OF GRAIN SIZE ON THE DUC-

(FORCES), BRITTLENESS, TESTS

This paper presents observations made regarding the influence of grain size on the catent of internal cracking and creep behavior of polycrystalline ice. The test material was infinally isotropic, laboratory prepared polycrystalline ice oran size ranged from 152 to 5.65 mm. Specimens were tested under constant load in uniaval compression with an initial stress of 2MPa and at a temperature of -5C. Optical positiest analysis showed that the estimated crack density varied over nearly three orders of magnitude as the grain size increased by a factor of three. The smallest-grained specimen exhibited no visible fractures the strain at the minimum ereep rate decreased significantly as the grain size, and hence the fracturing activity increased. These observations indicate that under the prevailing test conditions, the stated variations in grain size alone can initiate the duetile-to-brittle transition.

on a micro-mechanical explanation of the test results as well as the implications of the findings to areas of practical

A solid-state, durable, inexpensive radio frequency sensor (RFS) has been developed and laboratory-tested. The RFS uses a Wien bridge circuit to measure a change in soil impedance when changes in soil moisture occur. Both electrical conductance and capacitance are measured at differing moisture contents. The delectric constant of the soil moisture is proportional to the measured capacitance and is approximately linear with festored to execut moisture. is approximately linear with respect to percent mosture. Due to the simple readout system, the RFS has the potential to be interfaced to a data collection system for data acquisition. to be interfaced to a data collection system for data acquisition from remote areas. Preliminary tests on the temperature effect of the RFS accuracy have shown that volumetric water content can be obtained by the RFS over a wide range of temperatures. In addition to the soil moisture measurement, preliminary tests on the measurement of the liquid water-content of snow have been made. Comparison of the results with the calorimetric method indicate that the RF sensor can be used to measure snow water content. Since the RFS is soild state, it can be placed in remote areas and can monitor volumetric soil water content to within 0.5% by volume.

SAT, SNOW DEPTH.

Measurements of snow depth and its water equivalent were obtained at 11 snow courses in the Allagash, Maine, are in conjunction with acquisition of five Landsat-2 and -3 images during the 1977-78 and 1978-79 winters. Digital imagery data acquired on 31 May 1978, when the land was snow-free, was used to classify land cover categories. Ground truth water equivalent measurements of snow were area-weighted using the land cover classification to derive regional mean water equivalent values for snow cover on each of the five Landsat scenes. The 1 March 1978 snow measurement of 19.46 cm of water equivalent was used as an input value to the SSARR (Streamflow Synthesis and Reservoir Regulation) model. The SSARR prediction for the 1 March-31 May 1978 time period was within 78% of the measured runoff for the initial baseflow period and within 67% for the spring melt recession period. However, the timing of six observed runoff peaks was off by 2 to 9 days. The magnitude of five of the predicted runoff peaks was within 75% of the recorded streamflow. Additional work on calibrating the basin peak timing and melt rate factors is underway. factors is underway.

MP 1692 UTILIZATION OF THE SNOW FIELD TEST SERIES RESULTS FOR DEVELOPMENT OF A SNOW OBSCURATION PRIMER.

Ebersole, J.F., et al, Aug. 19. SR 83-31, Snow symposium, 3rd, Hanover, NH, Aug. 9-10, 1983. Proceedings, Vol.1, p.209-217, ADB-079 265, 21 refs. Aitken, G.W. 38-2137

58-2137 SNOW OPTICS, ATTENUATION, SNOWFALL, BLOWING SNOW, SNOW DENSITY, ICE CRYS-TAL STRUCTURE, WAVE PROPAGATION, VISI-BILITY, MILITARY OPERATION, NAVIGA-TION, SNOWDRIFTS, METEOROLOGICAL FACTORS.

The attenuation of electro-optical (EO), infrared (IR), and millimeter wave (MMW) energy through the atmosphere in conditions of low visibility due to the presence of falling or blowing snow can present serious problems for the effective use of surveillance and target acquisition systems. This paper discusses development of a snow obscuration primer for use by the Smoke and Aerosol Working Group (SAWG) of the Joint Technical Coordinating Group for Munitions for use by the Smoke and Acrosol Working Group (SAWG) of the Joint Technical Coordinating Group for Munitions Effectiveness (JTCG/ME). A key part of this primer is incorporation of test results obtained in the SNOW-ONE. -ONE-A, and ONE-B field trials. This includes measurements of falling and blowing sinow obscuration effects on EO IR MMW systems, both active and passive. An important aspect of this work, reported in this paper, is the evolution of a basis for developing "rules-of-thumb" for operation in air-borne-snow environments.

MP 1693 INCREASED HEAT FLOW DUE TO SNOW COMPACTION: THE SIMPLISTIC APPROACH. Colbeck, S.C., Aug. 1983, SR 83-31, Snow symposium, 3rd, Hanover, NH, Aug. 9-10, 1983. Proceedings, Vol.1, p. 227-229, ADB-079, 265, Extended summary. 2 38-2138 2 refs.

SNOW COMPACTION. HEAT TRANSFER. SNOW HEAT FLUX, SNOW COVER STRUCTURE. SURFACE TEMPERATURE. MATH-EMATICAL MODELS

When snow is compacted by foot or vehicle traffic, the compacted areas are visible on infrared images for some time. A simple model is used to calculate the temperature difference between the compacted and uncompacted snows The results are given as temperature difference sersus snow

MP 1594 USE OF LANDSAT DATA FOR PREDICTING SNOWMELT RUNOFF IN THE UPPER SAINT JOHN RIVER RASIN.

Merry, C.J., et al, International Symposium on Remote Sensing of Environment, 17th, Ann Arbor, Mf, May 9-13, 1983. Proceedings, Ann Arbor, Environmental Research Institute of Michigan, 1983, p.519-533, 16 refs. p.519-555, 10 1011. Miller, M.S., Pangburn, T.

JOHN RIVER.

To test a hypothesis that Landsat reflected radiance values on a regional scale do change, histograms of the Landsat MSS band 7 reflected radiance values for a 300 x 300 pixel (420 sq km) area near Allagash, Maine, were evaluated to quantify the change. A statistical description (skewness and kurtosis) of the histogram for each scene was developed and then correlated with ground measurements of snow depth. A snow index based on skewness and modal population was found to correlate well with snow depth. Following these initial results, the Landsat data were reexamined and corrections were made for solar elevation and MSS sensor. these initial results, the Landsat data were reexamined and corrections were made for solar elevation and MSS sensor calibration. The reflected radiance from open areas showed a consistent increase in intensity with increasing snow depth. The forested land cover classes did not change with snow depth. The ground truth measurements of water equivalent were area-weighted by the May land cover classification to derive mean regional water equivalent values for each of the five Landsat winter scenes. The 1 March 1978 estimate of 7.66 inches for snow water equivalent was used as input to the SSARR model for prediction of runoff during the 1 March through 31 May 1978 time period

A test site in the Cape Flattery area of northwest Washington state was selected for constructing a simulated data set to evaluate techniques for extracting topography from side-lookevaluate techniques for extracting topography from side-looking satellite systems. A negative transparency orthophotoquad was digitized at a spacing of 85 micron, resulting in an equivalent ground distance of 986 m between pixels and a radiometric resolution of 256 levels. A bilinear interpolation was performed on U.S. Geological Survey digital elevation model (DEVI) data to generate elevation data at a 9.86 m resolution. The nominal orbital characteristics and geometry of the SPOT (Système Probatoire d'Observation de la Terre) satellite were convoluted with the data files to produce simulated panchromatic HRV (High Resolution Visible) digital stereo imagery for three different orbital paths. Techniques were developed for reconstructing topographic data. Essentially, these techniques coalign a nadir and offnadir pass to calculate the stereo displacement for each pixel in the nadir view by correlating a small subarea to a corresponding the nadir view by correlating a small subarea to a corresponding subarea in the off-nadir pass—Preliminary analyses with the simulated HRV data and "test pattern" data verify the efficacy of this technique

LIME STABILIZATION AND LAND DISPOSAL OF COLD REGION WASTEWATER LAGOON SLUDGE.

Schneiter, R.W., et al. 1982, 7(3), p.207-213, 30 refs. Middlebrooks, E.J., Sletten, R.S.

WASTE TREATMENT, WATER TREATMENT, LIMING, SLUDGES, RECLAMATION.

LIMING, SLUDGES, RECLAMATION.

Effects of lime (Ca(OH)2) stabilization upon the pathogenic population in accumulated solids associated with the operation of two acrated wastewater lagoons in Alaska and two facultative wastewater lagoons in northern Utah were evaluated. The subsequent drying, at a temperature of 12C, of the lime stabilized sludges on sand and soil beds was also investigated by dosing the sludges with lime and applying sludges to bench scale drying beds. Lime addition produced high feeal coliform reduction, and the limed sludges readily dewatered on both sand and soil beds.

MP 1697 CALCULATION OF ADVECTIVE MASS TRANS-

PORT IN HETEROGENEOUS MEDIA.
Daly, C.J., U.S. Army Research Office, Report No.83-1, Conference of Army Mathematicians, 28th, (1983). Transactions, (1983), p.73-89, 12 refs. 38-2506

POROUS MATERIALS, MASS TRANSFER, GROUND WATER, FLUID DYNAMICS, ANALYSIS (MATHEMATICS).

A coupled analytical/numerical procedure for prediction of solute transport in heterogeneous media is described. The procedure consists of an analytic solution of the hydraulic equations, followed by a numerical solution for solute transport using the method of characteristics. The characteristics are determined by fourth-order Runge-Kutta and predictor-corrector algorithms. Accuracy of solute transport calculation is enhanced by the fact that fluid velocity can be directly obtained at a priori undetermined points in the flow field. The solute transport process is considered to be entirely advective, neglecting the effects of mechanical dispersion and molecular diffusion. Evidence is presented to demonstrate that purely advective processes in both heterogeneous and homogeneous media; can produce large "apparent dispersion." Such dispersion is shown to be easily capable of overwhelming any reasonable estimates of dispersion or diffusion based upon laboratory analyses of homogeneous media. For groundwater contamination problems, it is concluded that precise definition of the spatial variability of hydraulic properties is crucial to the accurate determination of the trajectory of contaminated waters.

CHARACTERISTICS OF MULTI-YEAR PRES-SURE RIDGES.

Koyacs, A., International Conference on Port and Ocean Engineering under Arctic Conditions, 7th, Hel-sinki, Finland, April 5-9, 1983. Proceedings, Vol.3, Espoo, Valtion teknillinen tutkimuskeskus, 1983, p.173-182, 13 refs. 38.2727

PRESSURE RIDGES, ICE FLOES, ICE FORMA-TION, OFFSHORE STRUCTURES, ICE PRESSURE, ICE STRENGTH, HUMMOCKS, COMPRESSIVE PROPERTIES, SEA ICE.

PRESSIVE PROPERTIES, SEA ICE.

Multi-year pressure ridges and thick hummock floes are the most severe ree formations that offshore structures will probably have to resist in the Beaufort and Chukchi Seas. Multi-year hummock fields 30 m thick have been measured near Prudhoe Bay, Alaska This paper presents information on 11 multi-year pressure ridges

The ridges were found to be voidless, and contained ice with a mean brine-free density of about 0.84 mg/cu m.

The apparent unconfined compressive strength was about 7 to 8 MPa at -10 C. The strength increased with depth below sea level, and, as expected, varied inversely with ice prossity. The sail-height-to-keel-depth ratios of these ridges are compared with observations made in the Beaufort and Chukchi Seas to show that the multi-year ridges in these areas have a relatively constant sail-height-to-keel-depth ratio of about 1 to 3.3.

SEA ICE, ICE CORES, ICE COMPOSITION, ALGAE, CRYOBIOLOGY, FRAZIL ICE, ANTARCTICA—WEDDELL SEA.

GAE, CRYOBIOLOGY, FRAZIL ICE, ANTARC-TICA.—WEDDELL SEA.

Ice cores obtained during October-November 1981 from Weddell Sea pack ice were analyzed for physical, chemical, and biological parameters.

Frazil ice, which is associated with dynamic, turbulent conditions in the water column, predominated (70%). Both floe thickness and salinity indicate ice which is less than 1 year old. Chemical analyses, particularly with regard to the nutrents, revealed a complex picture. Phosphate values are cattered relative to the dilution curve.

Nitrate and silicate values are lower than expected from simple scaling with salinity and suggest diatom growth within the ice. Nitrate values are higher in the ice than in adjacent waters. Frazil ice formation which probably concentrates algal cells from the water column into ice floes, esults in higher initial chlorophyll aby subsequent reproduction within the ice. Ice core chlorophyll ranged from 0.09 to 3.8 mg/cu m, comparable to values previously reported for this area but significantly lower than values for Antarctic coastal fast ice. The dominance of frazil ice in the Weddell is one of the major differences between this are and others. Consequently, we believe that ice structural conditions significantly influence the biological cummunities in the ice. (Auth)

An experimental study was undertaken to determine the dependence of crushing specific energy of urea ice on the aspect ratio (structure diameter/ice thickness) and the structure aspect ratio (structure diameter lice thickness) and the structure velocity. The experiments were conducted by pushing an instrumented, vertical, cylindrical structure into ice sheets at different velocities. Two parameters were vaned during the experimental program: diameter (50 to 500 mm) and velocity (10 to 210 mm/s). The urea concentration was changed slightly from 0.84 to 0.93% by weight. The results are presented graphically to show the dependence of the ratio of specific energy to unconfined uniaxial compressive strength on the aspect ratio for different ratios of velocity to ice thickness.

MOISTURE DETECTION, ROOFS, INFRARED PHOTOGRAPHY, TEMPERATURE MEASURE-MENT, INSULATION.

MENT, INSULATION.

Prior research by the Corps of Engineers has shown aerial thermography to be useful as a reconnaissance tool for finding wet roof insulation. This conclusion was based on findings from thermal line scanners flown at about 1000 feet in military fixed-wing aircraft and from hand-held thermal imagers flown at about 500 feet in military helicopters. During the spring of 1983 a comprehensive aerial to on-the-roof infrared comparison study was conducted on several roofs at Fort Devens, Massachusetts. These recent studies confirm our earlier opinion that oblique thermography is generally of reconnaissance value only However, "straight-down thermography from either fixed-wing aircraft or from helicopters can be used to produce reasonably accurate maps were produced by thermal imaging systems in a helicopter hovering as close as 200 feet above a roof. This study suggests that some forms of airborne thermography can be of more value than just a reconnaissance tool in finding wet roof insulation of course, a visual examination of each roof along with a few core samples are still needed before recommendations for maintenance and repair can be made.

Permafrost is generally divided into two tones from north to south continuous and discontinuous. At its southern limit, permafrost in Alaska exists in isolated masses under peat. In the northern portion of the continuous zone,

permafrost occurs everywhere near the surface of the entire permafrost occurs everywhere near the surface of the entire landscape with the exception of deep lakes and river channels. The presumed warming of the ground in the discontinuous zone due to CO2-induced climatic change will result in an areal reduction of permafrost. In the colder areas, continuous-zone permafrost temperatures will rise and summer action laws does how the contraction of the colder areas, active-layer depths will increase, but the spatial extent of permafrost will only be marginally affected. In both cases, where there is ground ice, thermal erosion and thaw consolidation will produce thermokarst terrain.

MODELING RAPIDLY VARIED FLOW IN TAIL

CAL MODELS, ELECTRIC POWER.

An understanding of the downstream propagation of sharpfronted, large-amplitude waves of relatively short period is important for describing rapidly varying flows in tailwaters of hydroelectric plants and following the breach of a dam We developed a numerical model of these waves by first identifying the primary physical processes and then performing an analysis of the solution. A linear analysis of the dynamic open channel flow equations provides relationships describing flow wave advection, diffusion, and dispersion in rivers. A one-dimensional diffusion wave model modified for application to tailwaters simulates the important physical processes and is straightforward to apply. is straightforward to apply.

ICE-RELATED FLOOD FREQUENCY ANALYSIS: APPLICATION OF ANALYTICAL ESTI-

Gerard, R., et al, International Specialty Conference on Cold Regions Engineering, 3rd, Edmonton, Alber-ta, April 4-6, 1984. Proceedings, (Edmonton, Uni-versity of Alberta, 1984), p.85-101, 12 refs. Calkins, D.J.

FLOOD FORECASTING, RIVER ICE, ICE JAMS, ICE CONDITIONS, ANALYSIS (MATHEMAT-

ICS).

In cold regions ice-related floods can make a significant, and often dominant, contribution to the flood population. They should therefore be considered in a flood frequency analysis. However, in many instances, histonical data for this purpose is lacking. Resort must then be made to analytical estimates of ice-related flood stages. This paper describes the determination and application of such estimates for a site on the Missisquoi River near Richford, Vermont.

ICE, FREEZEUP, ICE FORMATION. ANALYSIS (MATHEMATICS), FORECASTING, AIR TEMPERATURE, WATER TEMPERATURE, CANADA—SAINT LAWRENCE RIVER.

An important element of the ice management in northern rivers is forecasting water temperatures to predict the time of ice formation. The freeze-up forecast provides needed information for planning flow regulations and scheduling of the close of a navigation season. In this paper, the relationship between variations of air temperature and water relationship between variations of air temperature and water temperature is analyzed. An analytical expression for water temperature is obtained through the solution of a simplified convection-diffusion equation. The air temperature is repre-sented as a combination of a harmonic function and short term fluctuations. The short term fluctuations are deter-mined from National Weather Services forecasts.

CRYSTAL STRUCTURE, MODELS, SALINITY.

A layer of unfrozen water exists between the soil particle surface and the solid ice phase in a frozen soil at temperatures of practical concern This layer owes its existence to the effect of field forces associated with the soil particle surfaces. Its thickness depends on factors such as temperature, solute concentration and specific surface area. Additional unfrozen water occurs within the polycrystalline pore ice as well. The thickness of the unfrozen water layer strongly affects the mechanical behavior of the soil-ice interface and, hence, the gross mechanical proporties of the frozen strongly arrects the mechanical behavior of the soil-ce interrace and, hence, the gross mechanical properties of the frozen soil The total unfrozen water content is particularly useful since it reflects the contributions from a number of sources to the unfrozen water layer thickness. As a consequence, the unfrozen water content provides an excellent means for temperature, salinity and specific surface area.

SELF-SHEDDING OF ACCRETED ICE FROM HIGH-SPEED ROTORS

Itagaki, K., 1983, 83 WA HT-68, p.1-6, 16 refs.

ICE REMOVAL AIRCRAFT ICING. PROPEL-LERS, ICE ACCRETION, SUPERCOOLED FOG, ICE ADHESION, ICE SOLID INTERFACE, SUR-FACE ENERGY, ICE CRACKS, ICE COVER THICKNESS, HELICOPTERS, ANALYSIS ANALYSIS (MATHEMATICS)

Ice accreted on high-speed rotors operating in supercooled fog can be thrown off by centrifugal force, causing severe unhalance and creating dangerous projectiles. A simple force balance analysis indicates that the strength of accreted ice (and its adhesive strength) can be obtained by measuring the thickness of the accretion, the location of the separation, and the density. Such an analysis was applied to field and laboratory observations of self-shedding events. The results agree reasonably well with other observations.

ASYMPTOTIC BEHAVIOUR OF SOLUTIONS TO THE PROBLEM OF WETTING FRONTS IN ONE-DIMENSIONAL, HORIZONTAL AND IN-FINITE POROUS MEDIA.
Nakano, Y., June 1983, 6(2), p.71-78, 26 refs.

POROUS MATERIALS, SOIL WATER, DIFFU-SION, WETTABILITY, ANALYSIS (MATH-EMATICS), WATER CONTENT, EXPERIMEN-TATION

TATION.

The rsymptotic behavior of solutions to the problem of writing frosts is studied in one-dimensional, horizontal and infinite porous media with the soil-water diffusivity proportional to sonce power of the water context. The uniqueness of the similarity solution for the problem is studied and the properties of this solution are presented. It is shown that the similarity solution is an asymptotic solution of a wide class of initial value problems of writing fronts in the media. The use of the similarity solution is discussed for the experimental determination of the soil-water diffusivity.

SIMILARITY SOLUTIONS TO THE SECOND BOUNDARY VALUE PROBLEM OF UN-SATURATED FLOW THROUGH POROUS MEDIA.

Nakano, Y., Dec. 1983, 6(4), p.205-213, 26 refs. 38-3568

POROUS MATERIALS, WATER FLOW, BOUND-ARY VALUE PROBLEMS, SOIL WATER, DIFFU-SION, WATER CONTENT, ANALYSIS (MATH-EMATICS).

EMATICAL
Similarity solutions to the second boundary value problem
of unsaturated flow are studied in one-dimensional, semiinfinite perous media with the solu-rater diffusivity proportionat a same moner of the water content. The existence al to some power of the water content. The existence and uniqueness of two types of similarity solutions to the problem are investigated and the properties of these solutions are presented. It is shown that these two types of similarity solutions exist and that they may not be unique for every parameter range studed. The use of the similarity solutions is documed for the experimental determination of soil-water distinctions.

MP 1727 TEMPERATURE STRUCTURE AND INTER-FACE MORPHOLOGY IN A MELTING ICE-WATER SYSTEM.

Yen, Y.-C., Frontiers in hydrolegy, Littleton, CO, Water Resources Publications, 1984, p.305-325, 22 refs

38-3800 ICE MELTING, ICE WATER INTERFACE, MELTING POINTS, HEAT TRANSFER, TEMPERATURE DISTRIBUTION, WATER TEMPER-ATURE, BOUNDARY LAYER, CONVECTION, TURBULENT FLOW.

Nineteen tests were conducted with temperature measurements Nineten tests were conducted with temperature measurements at various stages of meiting experiments. Fourteen sets of photos were taken at various stages of the experiment for meiting from "sove. Formation of concentre ridges was observed only for higher warmer boundary temperatures. However, there were more sharp-edged cavities at lower warm boundary temperatures as compared to those at warmer temperatures. The seewater interface seemed to be much smoother at the junction of the cells in melting from below. These phenomena may be explained in that, in melting from above, the convective motions originate near the water-see interface and therefore, may possess a greater intensity.

MP 1728 EFFECTS OF VOLUME AVERAGING ON SPEC-TRA MEASURFD WITH A LYMAN-ALPHA HY-GROMETER.

Andreas, E.L., Apr. 1981, 20(4), p.467-475, 24 refs. 38-3865

HYGROMETERS, HUMIDITY, SPECTROS-COPY, MEASURING INSTRUMENTS, ANAL-YSIS (MATHEMATICS), VOLUME, ACCURACY YMM (MATHEMATICM), VOLUME, ACCURACY, Because the Lyman-siphs hygrometer averages turbulent fine-tuntions in himselfly over a right circular cylinder, the spectral response of the instrument degrades at higher wavenumbers. This paper contains a derivation of the three-dimensional spectral averaging function and uses this function, with a new model for the scalar spectrum, to numerically evaluate how this spatial averaging affects measured humidity spatial averaging affects measured humidity spraneter and humidity variance dissipation rates. In general, hygrometer parameters can be chosen that allow spectral measurements or moderately high wavenumbers, but with the use of security ever parameters can be consent that show spectral measurements to moderately high wavenumbers, but with the sure of source and detector tubes currently in the, an accurate measurement of the humidity variance descipation rate appears impossible

LOCATING WET CELLULAR PLASTIC INSU-LATION IN RECENTLY CONSTRUCTED ROOFS.

35-131 CELLULAR PLASTICS, ROOFS, INSULATION, MOISTURE DETECTION, WETTABILITY, TEM-PERATURE MEASUREMENT.

PERATURE MEASUREMENT. Infrared scanners are quite successful in finding wet roof installing, especially boards of rapidly absorbing insulations like perfire, wood liber and librors glass. But wet areas develop more thouly and noneurotemly in the cellular plastic insulations, such as uterhaine, which are commonly used in near roofs. These differences can affect the outcome of an infrared survey of new roofs. To determine the feasibility of detecting inception wet insulation, several recently constituted toofs were examined thermographically. It was usually more difficult to find measure in new roofs containing cellular relation to find in severations cellular relation insulations than in sew roofs with

was usually more deficult to find monthly in new roofs containing cellular plastic insulations than in new roofs with more absorbent invulations. This increased defficulty is due to the some; rate of neiting and to the nonunderm manner of weiting of some of the cellular plastics. Perhic, wood fiber and fibrous glass insulations tend to become uniformly weit throughout an entire board, whereas montion restrictly concentrates at the perimeters of boards of some cellular plastic insulations. However, eight to ten months after constitutions, enough montions can be commerte in months of the perimeters of some cellular plastic insulations.

Since this moisture is concentrated in a small portion of each insulation board, much of it would probably be overlooked by a nuclear or capacitance grid survey.

VERMONT—OTTAUOUECHEE RIVER.

VERMONT—OTTAUQUECHEE RIVER.

The results of three winters of freeze-up measurements on the Ottauquechee River have shown that the ice production heat transfer coefficient calculated from the ice volume measurements is somewhat related to the severity of the freeze-up meteorological conditions. A very intense cold period of -22 C for two days just as the river water temperature reached 0.0 C produced much higher ice volumes for the same river reach than two other freeze-up periods, which had average air temperatures of -7 C over 10 to 12 days. The intense cold period created lighter ice discharges, which forced the leading edge to progress upstream at a faster rate than during other years. The lateral ice closure was found to be linearly related to the number of accumulated freezing degree-days. The data on lateral closure for this small river were also related to the freeze-up open channel flow velocity and, when combined with similar data from the Nelson River in Manitobs, produced a reasonable relationship. The slush ice also established an equilibrium flow area at several measured cross sections throughout the study reach.

MP 1739 FORCE MEASUREMENTS AND ANALYSIS OF

PORCE MEASUREMENTS AND ANALYSIS OF RIVER ICE BREAK UP.
Deck, D.S., Workshop on Hydraulics of Ice-Covered Rivers, Edmonton, Alta., June 1 and 2, 1982. Proceedings, [1982], p.303-336, 19 refs. 32-4015

ICE LOADS, ICE PRESSURE, STRUCTURES, ICE BREAKUP, RIVER ICE, ICE CONTROL, ICE BOOMS, ICE FORECASTING, ICE MECHANICS, FLOATING ICE, COUNTERMEASURES, FRA-ZIL ICE, DESIGN.

ZIL ICE, DESIGN.

Measurements were made near Oil City, Pennsylvania, diving February 1981 to evaluate the performance of a flow g ice control structure during an ice run on a shallow and steep stream, Oil Creek The primary objective of the structure was to assist in forming an early, stable ice cover upstream of Oil City that would prevent prolonged frazil ice generation. The control structure was a double timber ice boom. This paper focuses on the forces exerted on the structure during ice breakup. The forces transmitted to the ice co. in structure prior to breakup and during the ice run were monitored through a strain-gaged tension link, which had been incorporated into the design of the structure, and this ice force was recorded with respect to time.

FREEZING OF A SEMI-INFINITE MEDIUM
WITH INITIAL TEMPERATURE GRADIENT.
Lunardini, V.J., Mar 1984, 106(1), p.103-106, Revision of 37-2397. 12 refs.

38.4127 38-4127 SOIL FREEZING, STEFAN PROBLEM, HEAT TRANSFER, TEMPERATURE GRADIENTS, GEOTHERMY, HEAT BALANCE, THERMAL CONDUCTIVITY, ANALYSIS (MATHEMATICS). CONDUCTIVITY, ANALYSIS (MATHEMATICS). Exact solutions to problems of conductive heat transfer with solidification are rare due to the nonlinearity of the equations. The heat balance integral technique is used to obtain an approximate solution to the freezing of a semi-infinite region with a linear, initial temperature distribution. The results indicate that the constant temperature Neumann solution is acceptable for soil systems with a geothermal gradient unlers extremely long freezing times are considered. The heat balance integral will yield good solutions, with simple numerical work, even for nonconstant initial temperatures.

ICE ACTION ON TWO CYLINDRICAL STRUC-TURES.

Kato, K., et al, Mar. 1984, 106(1), p.107-112, 17 refs. For another source see 38-641 (MP 1643). Sodhi, D.S.

ICE LOADS, OFFSHORE STRUCTURES, ICE PRESSURE, ICE SOLID INTERFACE, EXPERIMENTATION.

PERIMENTATION.

Ice action on two cylindrical structures, located side by side, has been investigated in a small-scale experimental study to determine the interference effects on the ice forces generated during ice structure interaction. The proximity of the two structures changes the mode of ice failure, the magnitude and direction of ice forces on the individual structure, and the dominant frequency of ice force variations. Interference effects were determined by comparing the experimental results of tests at different structure spacings.

THERMAL PATTERNS IN ICE UNDER DY-

NAMIC LOADING. Fish, A.M., et al, 1983, Vol.430, p.240-243, 9 refs. Marshall, S.J., Munis, R.H.

38-4120 TRANSFER, ICE SPECTROSCOPY, ICE THER-MAL PROPERTIES, PLATES, TESTS.

MAL PROPERTIES, PLATES, TESTS.

Heat emission patterns in the infrared spectrum were discovered in ice subjected to cyclic loading. The ice plates used in the tests had a rectangular shape of 13 x 19 cm and a thickness of 2 cm. The plates were frozen to the platen of the testing apparatus to form a cantilever beam and were vibrated over a frequency range from 0.5 to 5 kHz at an ambient temperature of -4 C. The surface heat patterns were scanned by two thermal imaging systems with spectral band passes of 2-5.6 micron and 8-14 micron, and the heat patterns were recorded on Polarona tim and on videotape. The heat emission patterns first appeared at the fixed end of the ice plate and migrated gradually to the free end. The temperature difference between the ends was found to depend on the duration and frequency of excitation. The results of these tests indicate that vibrothermography can have wide areas of practical application in the study of the origin and growth of defects, recrystallization, fatigue, and failure processes in ice.

OFFSHORE OIL IN THE ALASKAN ARCTIC Weeks, W.F., et al, July 27, 1984, 225(4660), p.371-378, Numerous refs.

Weller, G. 38-4117

NATURAL RESOURCES, OFFSHORE DRILL-ING, OIL RECOVERY, SEA ICE, ICE LOADS, ICE SCORING.

SCORING.

Oil and gas deposits in the Alaskan Arctic are estimated to contain up to 40 percent of the remaining undiscovered crude oil and oil-equivalent natural gas within US jurisdiction Most (65 to 70 percent) of these estimated reserves are believed to occur offshore beneath the shallow, ice-covered seas of the Alaskan continental shelf. Offshore recovery operations for such areas are far from routine, with the primary problems associated with the presence of ice. Some problems that must be resolved if efficient, cost-effective, environmentally safe, year-round offshore production is to be achieved include the occurate estimation of ice forces on offshore structures, the proper placement of pipelines beneath ice-produced gouges in the sea floor, and the cleanup of oil spills in pack ice areas. BOTTOM SEDIMENT, SEDIMENT TRANSPORT, REMOTE SENSING, WATER POLLUTION, SPECTROSCOPY, DISTRIBUTION.
Simulated SPOT (HVR) 20-m multispectral data were obtained on 7 July 1984 over the Hart-Miller Island diked spoil containment facility located in the upper Chesapeake Bay Sediment plumes were clearly visible and indicated the sediment transport direction at the time the image was taken. The portion of the image along the bay side of the island had strong specular reflection. The image was preprocessed to remove the majority of the specular reflection. The Sobel operator was applied to the enhanced simulated SPOT image. A set of edge segments were generated that follow the boundaries of the major sediment plumes. The strength of the edges was quite variable, reflecting the varying diffusion of the plume border. The Sobel edge-enhanced image showed two sets of plumes. The sobel edge-enhanced image showed two sets of plumes. The sobel edge-enhanced image showed two sets of plumes. The sobel edge-enhanced image showed two sets of plumes. ED STATES—ALASKA—TANANA RIVER.

The Alaska District, Corps of Engineers initiated a program called the Tanana River Monitoring and Research Program to determine if any adverse impacts are occurring or may occur as a result of Phase III construction of the Chena Flood Control Project. The results of the monitoring efforts and a preliminary analysis of the Phase III construction are presented in this report. Aerial photography and river cross-sections were used to document historical changes from 1961 to 1981. Riverbank erosion and channel changes before and after the Phase III construction are evaluated to determine the effects of the construction on the natural river process

MP 1746 RELATIONSHIPS AMONG BANK RECESSION, VEGETATION, SOILS, SEDIMENTS AND PER-MAFROST ON THE TANANA RIVER NEAR FAIRBANKS, ALASKA.

Gatto, L.W., Overview of Tanana River monitoring and research studies near Fairbanks, Alaska. Prepared by U.S. Army Cold Regions Research and Engineering Laboratory, U.S. Army Corps of Engineers, Jan. 1984, 59p., Appendix B. 30 refs.

BANKS (WATERWAYS), SOIL EROSION, FLOOD CONTROL, VEGETATION, PERMA-FROST BENEATH RIVERS, SEDIMENTS, UNIT-ED STATES—ALASKA—TANANA RIVER.

ED STATES—ALASKA—TANANA RIVER.

The objective of this analysis was to determine if available data are useful in identifying the characteristics that contribute to erodibility of the banks along two reaches of the Tanana River Existing data on bank vegetation, soils, sediments and permafrost were used. Because these data were general and not collected for the purpose of site-specific analysis, my analytical approach was simple and did not include any statistical tests. The data were visually compared to the locations and estimated amounts of historical recession to evaluate if any relationships were obvious

BANK RECESSION AND CHANNEL CHANGES IN THE AREA NEAR THE NORTH POLE AND FLOODWAY SILL GROITS, TANANA RIVER,

ALBEDO, SEA WATER.

Sensitivity simulations of a hierarchy of Antarctic sea ice models to atmospheric warming are carried out and analyzed. The study includes models with only a thermodynamic ice cover, models with inisitu leads but no ice transport, and a fully coupled dynamic/thermodynamic model that includes transport, leads and strength-thickness coupling. All models employ a 60-m-thick oceanic mixed layer, together with a spatially and temporally varying heat flux into the mixed layer from the deep ocean. The heat flux was generated interactively by using a fixed fraction of the ice growth and cooling rates from the full dynamic/thermodynamic model the same spatially and temporally varying heat flux fields were used in all sensitivity simulations. Models including full ice dynamics effects are found to be less sensitive to atmospheric warming than thermodynamics-only models, while atmospheric warming than thermodynamics-only models, while models with specified lead fractions are more sensitive than thermodynamics-only models (Auth. mod.)

PROJECTILE AND FRAGMENT PENETRA-TION INTO ORDINARY SNOW.

Swinzow, G.K., Hanover, NH, U.S. Army Cold Regions Research and Engineering Laboratory, 1977, 30p., Unpublished manuscript. 10 refs.

PROJECTILE PENETRATION, SNOW COVER EFFECT, MILITARY OPERATION, SNOW DEN-SITY, MILITARY ENGINEERING, PROTEC-TION, PENETRATION TESTS, PHOTOGRAPHY. TION, PENETRATION TESTS, PHOTOGRAPHY. A soldier on the battlefield is told to "dig in" to protect imself against projectiles and fragments But in cold regions or seasons the ground may be hard, suitable only for deliberate field fortifications built using machines and explosives. However, a winter battlefield scenario often contains an excellent protective material: the snow cover Often neglected or considered a nuisance, snow can be an obstacle and a disadvantage for the ignorant and a decisive advantage for the properly trained and knowledgeable soldier. Construction of a protective structure made of ordinary snow requires an order of magnitude less effort in time, manpower and energy than is required to obtai, the same amount and energy than is required to obtain the same amount of protection by using sand bags or by "digging in" We have found that small arms projectiles penetrate only 2 m into a snowpile and that protection against recoilless rifle ammunition (HEAT) of the shaped charge type requires less than 4 m of ordinary snow Our findings indicate that energy to penetration depth relations are complex and that point detonating fuzes may present greater difficulties in snow covered terrain

SIMPLE BOOM ASSEMBLY FOR THE SHIP-BOARD DEPLOYMENT OF AIR-SEA INTERACTION INSTRUMENTS.

Andreas, E.L., et al, 1984, 11(3), p 227-237, For another source see 38-868 or 13G-28929 21 refs. Rand, J.H., Ackley, S.F.

MARINE METEOROLOGY, METEOROLOGI-CAL INSTRUMENTS, MEASURING INSTRU-MENTS, BOOMS (EQUIPMENT), SHIPS, AN-TARCTICA

TARCTICA
We have developed a simple boom for use in measuring meteorological variables from a ship. The main structural member of the boom, a triangular communications tower with rollers attached along its bottom side, is deployed horizontally from a long. flat deck, such as a helicopter deck, and will support a 100-kg payload at its outboard end. The boom is easy to deploy, requires minimal ship modifications, and provides ready access to the instruments mounted on it. And because it is designed for use with the ship crosswind, oceanographic work can go on at the same time as the air-sea interaction measurements. We describe our use of the boom on the Mikhail Somov during a cruse into the Antiarctic sea ice and present some representative measurements made with instruments mounted on it. Theory, experiment, and our data all imply that instrument seployed windward from a rear helicopter deck can reach air undisturbed by the ship. Such an instrument site has clear advantages over the more customary mast, bow, or buoy locations. or buoy locations (Auth)

SNOWSTORMS, SNOW DEPTH, SNOWFALL, SYNOPTIC METEOROLOGY, METEOROLOGI-CAL DATA.

This paper contains a detailed description of meteorological conditions (including upper air) of an intense Northeast snowstorm that occurred in mid-December 1981. The paper relates the on-site meteorology to the overall concurrent synoptic situation. Consideration is given to air mass, hydrometeor intensity, visibility and crystal habit along the SNOW-ONE-A primary line-of-site.

FALLING SNOW CHARACTERISTICS AND EX-

TINCTION.
Berger, R.H., Mar. 1983, No.83-04, Snow Symposium ol.1, p.61-69, ADB-073 046, 2 refs 38.4309

SNOWFALL, LIGHT TRANSMISSION, PARTI-CLE SIZE DISTRIBUTION, PRECIPITATION GAGES, LIGHT SCATTERING.

An examination of the literature shows that a single relationship An examination of the literature shows that a single relationship between the extinction and the precipitation rate does not exist for snow as it does for rain. This is due in part to the wide range of particle sizes and shaper which determine both the optical and mechanical properties of snow. The extinction measurements and extensive snow characterization made during the SNOW-ONE and SNOW-ONE-A field experiments provide the data for an examination of the dependence of the extinction on various snow characteristics. The correlations between the extinction and several snow characterization parameters are presented.

VISIBLE PROPAGATION IN FALLING SNOW AS A FUNCTION OF MASS CONCENTRATION AND CRYSTAL TYPE.

Lacombe, J., et al, Mar. 1983, No 83-04, Snow Symposium 2, Vol.1, p 103-111, ADB-073 046, 8 refs Koh, G., Curcio, J A

LIGHT TRANSMISSION, ATTENUATION, SNOWFALL, SNOW CRYSTAL STRUCTURE, SNOW OPTICS, OPTICAL PROPERTIES, DENSITY (MASS/VOLUME).

At SNOW-ONE-A mass concentration of falling snow was At SNOW-ONE-A mass concentration of failing snow was measured in conjunction with measurements of visible transmittance and observations of snow crystal type. An examination of a significant portion of the resulting data base reveals that a general correlation exists between visible attenuation and snow concentration. The data also indicate that crystal habit is a major factor affecting the relationship between afternishing and concentration. attenuation and concentration

MP 1758 FREE WATER MEASUREMENTS OF A SNOW-PACK

Fisk, D.J., Mar. 1983, No.83-04, Snow Symposium 2, Vol.1, p 173-176, ADB-073 046, 2 refs.

SNOW WATER CONTENT, TEMPERATURE MEASUREMENT, UNFROZEN WATER CONTENT, SNOW MELTING, CALORIMETERS.

A review is given of methods (melting and freezing calorimetry) previously used for measuring the free water content of snow on the ground. Their merits and faults are described A new method, developed by the author, based on the temperature depression observed when a snow sample is completely dissolved in ethanol, is described and compared to the meiting and freezing calorimetric methods.

PERFORMANCE AND OPTICAL SIGNATURE OF AN AN/VVS-1 LASER RANGEFINDER IN FALLING SNOW: PRELIMINARY TEST RE-SULTS.

Lacombe, J., Mar. 1983, No.83-04, Snow Symposium 2, Vol.1, p.253-266, ADB-073 046, 10 refs.

An AN/VVS-1 pulsed ruby laser rangefinder was operated during the February 9, 1982 snow storm at SNOW-ONE-A. The device's digital readout was monitored as the system ranged over known distances to several targets. System performance has been evaluated relative to detailed measurements of airborne-snow concentration, precipitation rate and visible transmittance. rate and visible transmittance Observations of the rangefinder's optical signature have been made using a video camera and still photography This work was accomplished during both clear-air and light-snowfall conditions

CHEMICAL OBSCURANT TESTS DURING WINTER: ENVIRONMENTAL FATE.
Cragin, J.H., Mar. 1983, No.83-04, Snow Symposium 2, Vol.1, p.267-272, ADB-073 046, 3 refs. 38-4325

SNOW OPTICS, INFRARED RECONNAIS-SANCE, AEROSOLS, CHEMICAL ANALYSIS, POLLUTION, TEMPERATURE EFFECTS, SAM-PLING, TESTS

PLING, TESTS

Concentrations of orthophosphate, IR1 and IR2 obscurants were measured in surface snow samples after a wintertime test of white phosphorus (WP) smoke and the two infrared exponentially downwind from the smoke release point. Orthophosphate concentrations were all less than the analytical detection limit of 0.15 mg/L. Quantities of smoke released pose no hazard to the public or environment. Snow was found to provide a clean non-contaminating surface upon which to collect the deposited aerosol.

ON SMALL-SCALE HORIZONTAL VARIA-TIONS OF SALINITY IN FIRST-YEAR SEA ICE. Tucker, W B, et al, July 20, 1984, 89(C4), p.6505-6514, 20 refs

Gow, AJ, Richter, J.A

SEA ICE, ICE SALINITY, BRINES, VARIATIONS. SEATCE, ICE SALINITY, BRINES, VARIATIONS.

Measurements of salinity over horizontal distances of 38 to 76 cm in a thick first-year ice sheet have revealed significant differences. A maximum salinity difference of 2 per mill was observed between ice core segments from the same depth. The mean standard deviation for 10-cm thickness increments through the 20-m ice sheet was 0.39 per mill between the five closely spaced cores. The most likely mechanisms for these significant differences in salinity over short distances is differential brine drainage in the ice sheet due to varying locations of brine drainage channels. A simple one-dimensional model which assumes a normally simple one-dimensional model which assumes a normally distributed arrangement of brine drainage channels provides results consistent with the horizontal differences observed (Auth.)

ICE COVER MELTING IN A SHALLOW RIVER. Calkins, D.J., June 1984, 11(2), p.255-265, With French summary. 9 refs.

105-36-401 ICE MELTING, RIVER ICE, ICE JAMS, HEAT TRANSFER, FRAZIL ICE, WATER TEMPERATURE, RIVER FLOW, FREEZING POINTS, DIURNAL VARIATIONS, TEMPERATURE DISTRIBUTION. BUTION.

URNAL VARIATIONS, TEMPERATURE DISTRIBUTION.

The heat transfer coefficients computed from field data on both ice cover melting and water temperature attenuation are higher than the values one would compute based on extrapolation of previous laboratory flume data. The computed heat transfer coefficients were relatively consistent when calculated from the water temperature decay data. Consistent results were also obtained with one set of very detailed ice cover melting data. The diurnal fluctuation in water temperature from the freezing point to values of 0.4-0.6 C was associated with the incoming solar radiation and the open water surface area. The measured water temperature distribution beneath the ice cover at a particular cross section varied from 0.2 to 0.6 C due to the influence of frazil ice and flow distribution. In the open water reaches the water temperature was essentially fully mixed vertically but lateral variation across the river ranged from 0.1 to 0.3 C. The average daily melting of the ice cover often exceeded 5.0 cm and at some locations the rate was as high as 8 cm/d. The melt was not uniform scross the section but was highly dependent upon the flow conditions, velocity, and depth. The ice cover melting for this year only occurred during the daylight hours as the air temperature likewise decayed to its freezing point.

SURFACE ROUGHNESS OF ROSS SEA PACK TCE.

Govoni, J.W., et al, 1983, 18(5), p.123-124, 5 refs. Ackley, S.F., Holt, E.T. 39-16

SEA ICE, PACK ICE, ICE SURFACE, MEASUR-ING INSTRUMENTS, ANTARCTICA-SEA.

At the end of the 1980 austral winter, sea-ice surface roughness was assessed along selected tracks in the Ross Sea. The ice surveyed consisted mannly of first-year pack ice. Surface profiles were made using a Spectra-Physics Geodolite 3A laser profilometer which was mounted vertically in the camera bay of a National Science Foundation LC-130 aircraft. The profilometer, recording equipment and measurement technique are described. For the data analyzed to date, the Ross Sea region appears in general to have much less ridging than either the Weddell Sea or the Arctic Basin. The open nature of the boundaries here leads to generally divergent conditions and diminishes the stress transmitted through the pack ice resulting in fewer high ridges. Near costal boundaries, however, localized high stress may exist and ridging features develop accordingly. At the end of the 1980 austral winter, sea-ice surface roughness

A dynamic-thermodynamic spaciec model (Hibler 1979) is used to simulate northern hemisphere sea ice for a 20-year period, 1961 to 1980. The model is driven by daily atmospheric grids of sea-level pressure (geostrophic wind) and by temperatures derived from the Russian surface temperature data set. Among the modifications to earlier formulations are the inclining and by temperatures derived from the Russian surface tempera-ture data set. Among the modifications to earlier formula-tions are the inclusion of snow cover and a multilevel ice-thickness distribution in the thermodynamic computations. The time series of the simulated anomalies show relatively large amounts of ice during the early 1960s and middle 1970s, and relatively small amounts during the late 1960s and early 1970s. The fluctuations of ice mass, both in the entire domain and in individual regions are more persustent. and early 1970s The fluctuations of ice mass, both in the entire domain and in individual regions, are more persistent than are the fluctuations of ice-covered area. The ice dynamics tend to introduce more high-frequency variability into the regional (and total) amounts of ice mass. The simulated annual ice export from the Arctic basin into the East Greenland. Sea varies interannually by factors of 3

(FORCES). A thermodynamic model has been developed that describes the entire creep process, including primary, secondary, and tertiary creep, and failure for both constant stress (CS) tests and constant strain rate (CSR) tests, in the form of a unified constitutive equation and unified failure criteria. Deformation and failure are considered as a single thermoactivated process in which the dominant role belongs to the change of entropy. Families of creep curves, obtained from uniaxial compression CS and CSR tests of froren soil, respectively footh presented in dimensionless coordinates), are plotted as straight lines and are superposed, confirming the unity of the deformation and failure process and the validity of the deformation and failure process and the validity of the model. A method is developed for determining the parameters of the model, so that creep deformation and the stress-strain relationship of ductile materials such as soils can be predicted based upon information obtained from either type of test

TIONS, DENSITY (MASS/VOLUME).

Uniaxial compressive strength tests were conducted on remolded, saturated Fairbanks frozen silt under various constant machine speeds, temperatures and dry densities. Test results show that the peak strength of frozen silt is not sensitive to dry density (or water content) at 2 C, especially at clatively high strain rates, but is very sensitive to temperature and applied strain rate. However, the failure strain is not sensitive to temperature and afrain rate within a wide range of strain, rate, but is very sensitive to dry density. It has been found that the initial yield strength consistently increases with decreasing dry unit weight. The initial increases with decreasing dry unit weight. The initial yield strain is almost independent of dry density and temperature, but varies with strain rate. The initial tangent modulus of frozen silt is found to be nearly independent of strain rate, but the 50% strength modulus is closely related to strain rate. The test results indicate that there is a definite relationship between the two moduli.

This paper presents the results of an investigation of microspherules found in snow and pack ice from the Weddell Sea, Antarctica, collected during the U.S.-U.S.S.R. Weddell Polynya Expedition, 1981. Elemental composition, size, and concentration of microspherules were determined using a scanning electron microscope (SEM) and energy dispersive X-ray analysis (BDXA). Typical textures of microspherules are shown in this report and compared with those found in snow and ice-fog crystals sampled from the Northern Hemisphere. In this study, 23 microspherules were found in the snow sample from the Weddell Sea and 6 from the snow-ice sample. The concentration of microspherules in the snow samples is calculated to be approx 0.001 percent, three orders of magnitude smaller than that of the Northern Hemisphere. This indicates that the concentration of microspherules in the Antarctic may be three orders of magnitude smaller than the concentration found in the Northern Hemisphere. Silicon- and titanium-rich microspherules from the Weddell Sea were found in fly ash of terrestiral origin. sphere. Sincon and the war found in fly ash of terrestrial origin. The iron rich microspherules were tentatively identified to be of extraterrestrial origin.

RESERVOIR BANK EROSION CAUSED BY

Gatto, L.W., Aug. 1984, 9(3), p.203-214, Refs. p.211-39.397

ICE EROSION, BANKS (WATERWAYS), RESERVOIRS, ICE CONDITIONS, WATER LEVEL, BOTTOM SEDIMENT, SHORE EROSION.

The purpose of this study was to evaluate the documented and potential importance of ice crosson along reservoir banks. The evaluation is based on a literature review and on inferences drawn from field observations and experience. Very little is known about the amount of reservoir bank crosson caused by ice action, although considerable information exists on to crosson processes along the shortclines and beaches of oceans, rivers and lakes The importance of ice-related crosson along a reservoir bank would depend primarily on water level, but ice conditions and bank sediment characteristics would also be important. If the reservoir water level ties would also be important. If the reservoir water level is at bank level, ice could directly erode a bank face. If the water is below the bank, ice would have no direct effect on it.

However, ice could indirectly increase bank instability by disrupting and eroding near-viore and beach zones, which could 'ead to bank erosion.

PRELIMINARY INVESTIGATION OF THER-MAL ICE PRESSURES.

Cox, G.F.N., Aug. 1984, 9(3), p.221-229, 16 refs.

ICE PRESSURE, ICE THERMAL PROPERTIES, STRESSES, RHEOLOGY, ICE TEMPERATURE, LAKE ICE, MATHEMATICAL MODELS, HY-DRAULIC STRUCTURES.

Measured ice stress data are needed to verify and improve thermal ice thrust prediction models used in estimating ice forces on dams, bridge piers, locks and other hydraulic structures. During February and March, 1983, thermal ice pressures were measured in the ice on a small lake in central New Hampshire. Even though the ice sheet was relatively warm and only exhibited small changes in temperature, stresses up to 200 to 300 kPa were recorded with a newly designed biaxial ice-stress sensor. Ice stresses normal and parallel to the shore of the lake were similar. Given the rate of change of temperature of the ice, ice pressures were calculated for the measurement period using a uniaxial rheological model consisting of a spring and nonlinear dashpot connected in sense Calculated and measured stresses were in good agreement. dashpot connected in series stresses were in good agreement

Small ferromagnetic particles in soils locally change the magnetic field of a nuclear magnetic resonance (NMR) analyzer. This causes a decrease in the NMR signal intensity when NMR is being used to measure unfrozen water contents in partially frozen soils or total water contents in thawed soils. We mixed Tuto clay, a soil containing no magnetic particles, with various small amounts of pure powdered magnetite, and determined the NMR signal intensity while the samples were both thawed and partially frozen. Then we derived an equation that correlates the thawed sample signal intensity with the weight percent of powdered magnetite added. The unfrozen water content of the partially frozen samples could be determined accurately for samples containing up to 0.2 to 0.3% magnetite. Several methods for demagnetizing soils containing large amounts of magnetic particles were tried, with the most effective found to be stirring a slutry of the soil over a powerful permanent magnet. Accurate unfrozen water contents could be determined for all the partially frozen samples is ower form of demagnetizing procedure was used on those samples containing the most magnetic naturels. procedure was used on those samples containing the most magnetic particles

WATER SUPPLY, WASTE DISPOSAL, SNOW COVER EFFECT, WASTE TREATMENT, WATER CHEMISTRY, EQUIPMENT, ICE MELT-

The snow and glacial ice on permanent snowfields must serve as both the water source and the receptacle for wastes for any human habitation. In addition, the snow also serves as the support media for any structural foundations and hence the thermal aspects of water supply and waste disposal can be critical. Most activity has occurred on the ice caps of Greenland and Antarctica and has ranged the ice caps of Greenland and Antarctica and has ranged from small transient field parties to large permanent facilities in continuous use for over 25 years. Novel procedures to insure the reliable production of good quality water are described as well as the recommended criteria for water quantity depending on the size and duration of the activity. The various methods of wastewater disposal that have been used at temporary camps and permanent stations are described along with the results from studies that defined the fate of the wastewater following its discharge to the snow. Such definition is important to insure protection of the water supply as well as the thermal integrity of any structural foundation. ICE JAMS, ICE CONTROL, RIVER ICE, FLOODING, ICE BOOMS, ICE BREAKUP, COUNTER-MEASURES.

This paper addresses the author's involvement at two areas where ice jam flooding has caused severe economic hardship and loss of life. An ice boom has been used to control the formation of niver ice at Oil City, Pennsylvania, and a permanent ice control structure will be constructed on Cazenovia Cree' in West Seneca, New York, to control the river ice during break-up.

SALMON RIVER ICE JAMS.

ICE JAMS, RIVER ICE, FLOODING, ICE CONDITIONS, FREEZEUP, ICE COVER THICKNESS, ICE CONTROL, MODELS, UNITED STATES—IDAHO—SALMON RIVER.

IDAHO—SALMON RIVER.

A study was undertaken to document the ice conditions leading to the ice jam flooding along the Salmon River in the vicinity of Salmon, Idaho.

This short paper documents the ice conditions on the river during the freeze-up period and the simple analytical model used to pieute the advance of the ice cover leading edge for cover thickness in excess of 9 ft (3 m) were measured at cross sections where shoving had occurred the initiation of the ice cover for this reach of the river begins in a long, deep pool formed by an alluvial fan from Dump Creek that developed in the late 1800's By improving the flow conveyance through the alluvial fan and increasing the flow velocity in the backwater behind it, the initiation of the freeze-up ice cover could be delayed, thereby delaying the arrival of the leading edge at Salmon, Idaho, and reducing the potential for ice jam flooding

MODELING INTAKE PEFORMANCE UNDER FRAZIL ICE CONDITIONS.

Dean, A.M., Jr., Conference ton Water for Resource Development, Coeur d'Alene, Idaho, Aug. 14-17, 1984. Proceedings, 1984, p.559-563, 5 refs.

WATER INTAKES, FRAZIL ICE, ICE CONDI-TIONS, WATER PIPES, ICING, MODELS, COUN-TERMEASURES.

A water intake was modeled in a refrigerated flume in an active frazil icing environment in order to evaluate alternative modifications to the prototype structure. Conduit dimensions tested were 2.7-in round, 4.6 in round, 6-in square, 8-in square, and 12-in square Entrance shapes tested were square, quarter-rounded, and elliptical Model flows varied from 50 gpm to 360 gpm, resulting in average model intake velocities of 0.8 fps to 2.8 fps. Corresponding Froude prototype velocities varied from 0.3 fps to 2.0 fps. The length scale varied from 1.65 to 1.16. Tests were run until a head was developed across the model intake which was equivalent to a 12 foot head on the prototype, or until the icing tendency of the structure was determined. The icing mechanism observed in the model included stoppering of the intake with ice masses, restriction of the intake with multiparticle masses, and gradual accumulation of frazilice particles on the intake. A water intake was modeled in a refrigerated flume in

TIONS, MODELS, MAPPING.

Two methods for computing basin areal average water equivalent of the snowpack based on point snow course measurements are discussed. One involves the use of a square grid databank of elevations and vegetation types which are regressed against snow water equivalent. The other method utilizes digital tapes of LANDSAT satellite imagery to delineate various vegetation categories throughout a basin. Snow-course values obtained within a given vegetation category are then distributed over the area within each basin which contains that category of vegetation. Where possible, the methods were checked by deriving snowpack values for six basins in the Upper Saint John River basin for the spring of 1978. These values were then used as input to the SSARR model, and the resulting runoff hydrographs were compared to those obtained using the conventional "isoline mapping" method of distributing the snowcourse values. Lastly, a range of errors were introduced into the conventional-stayl, derived snowpack values, and the resulting range in errors ly derived snowpack values, and the resulting range in errors of the runoff hydrographs were computed to determine the sensitivity of the SSARR model to errors in snowpack input.

Subarral sediment flow is the predominant process depositing diamictons at the terminus of Matanuska Glacier. Flows originate where sediments overlie glacier ice. Ablation of ice exposed in slopes disaggregates the overlying sediment and mixes it with meliwater and debris released simultaneously. of ice exposed in slopes disaggregates the overlying sediment and mixes it with meltiwater and debris released simultaneously. This material generally flows only after its strength is further reduced by excess pore pressures and seepage pressures generated by meltiwater from thawing ice. Moving sediment flows show reasonably systematic changes in physical attributes such as dimensions, texture, flow rates, density and erosional action, and in grain support and transport mechanisms that can be related to changes in the water content of their matrix material. At lowest water contents, flows support grains by their strength and move through shear in a thin zone at their base. Increased thicknesses of the zone in shear and deformation of other types accompany increased water contents, with grain interference and collisions, localized iquefaction and fluidization, transient turbulence, and bedload traction and saltation operating simultaneously in such moving flows. At highest water contents, flow appear fully liquefied. The fluidity of the sediment flow and the amount of water in the sediment flow channel determine the degree of preservation of the source flow's properties and the depositional morphology. Because mobilization of a sediment flow destroys the glacial sedimentary properties of its sediment source and, further, because the mechanics of transport and deposition develop new "non-glacial" properties in this sediment, the diamicton deposited in the glacial environment by sediment flow should not be called till

CANADA—SAINT LAWRENCE RIVER
A computer model was developed for simulating the formation of use cover in the Upper St. Lawrence River. The model included submodels for the river flow condition, the distribution of water temperature or fearli ice production, and the formation of an ice cover. Distributions of water temperature or ice production are determined by a Lagrangian solution of the equation for the transport of thermal energy subject to surface heat exchange. The formation of an ice cover and ice accumulations is formulated according to existing equilibrium ice jam theories. The hydraulic condition in the river system is determined by an implicit numerical solution of unsteady continuity and momentum equations.

A numerical model of the flow and ice conditions during freeze-up for the Ottauquechee River has been developed and calibrated with reasonable success A limited sensitivity analysis of the key ice hydraulic modeling coefficients and independent variables was undertaken to examine their effect independent variables was undertaken to examine their effect on the rate of leading edge progression, ice thicknesses and water levels. The criteria for advancement of the leading edge were based on both the entrainment velocity of incoming frazil slush at the leading edge and whether or not the flow condition was sub-critical just upstream of the leading edge. The depositional mode of ice thickness of the leading edge. The depositional mode of ice thickness in the steep reaches and over 80% in 1 km of the pool. The simulation suggests that the initial ice cover thickness during progression can be predicted using the equilibrium ice jam theory with a suitable cohesion coefficient. The inflow ice discharge and ice generated within the reach modeled were important and have to be known with reasonable accuracy to get good simulations of the ice thicknesses, water levels and ice cover progression.

MP 1816 RISE PATTERN AND VELOCITY OF FRAZIL

FRAZIL ICE, RIVER ICE, ICE MECHANICS. VELOCITY, TESTS, ARTIFICIAL ICE.

VELOCITY, TESTS, ARTIFICIAL ICE.

The objective of this study was to examine the rise pattern and velocity of frazil ice. In addition, discs made of other materials were employed both to facilitate this study and to aid in the development of artificial frazil for future transport studies. The rise velocity is a parameter important to the understanding of frazil entrainment, transport and deposition. Laboratory tests were conducted in a large clear plastic cylinder at controlled temperatures. The rise velocity of real frazil is compared with theory and given an indirect verification that the preferential crystal growth direction increases disc diameter while the thickness remains essentially constant. The effective drag coefficients and rise pattern stability are discussed in terms of a Reynolds-Stroubal number relationship. The results from real and artificial frazil experiments are compared, and criteria for frazil simulation are suggested.

MP 1817 RADAR MEASUREMENTS OF BOREHOLE GEOMETRY ON THE GREENLAND AND AN-TARCTIC ICE SHEETS.

TICA—DOME C.

A method for measuring the geometry of borcholes in glaciers has been developed and tested in Greenland and Antactica Coordinates of points along the borchole are determined by lowering a passive radar target into the borchole and then tracking the target from three surface stations. Comparison of geometry interpreted from radar data and from a conventional inclinometry experiment indicates that radar data can be used to estimate average borchole inclination and arimuth but cannot be used to measure details of the borchole geometry that are revealed by conventional inclinometry surveys. Random error introduced by variations in the physical properties of the glacier and electrical noise in the radar unit limit measurement accuracy, but the accuracy can be improved by establishing additional surface radar stations around the borchole. These experiments demonstrate the utility of the radar method and suggest the possibility of deploying permanently installed radar targets in ice sheets of deploying permanently installed radar targets in ice sheets to measure intraglacial movements. (Auth.)

WEST ANTARCTIC SEA ICE.

Ackley, S.F., Environment of West Antarctica: potental CO2-induced changes, report of a workshop, July 1983, Washington, D.C., 1984, p.88-95, PB85-110 757, 14 refs. 39-1502

SEA ICE, ICE COVER EFFECT, CLIMATIC CHANGES, CARBON DIOXIDE, HEAT TRANS-FER, ANTARCTICA—AMUNDSEN SEA, ANTARCTICA—ROSS SEA.

In constructing models for predicting antarctic sea ice effect on global climate, temperature and wind fields over and below the pack ice must be analyzed. These elements affect the maximum extent of the ice pack and the ice dynamics in the pack strongly modulates the CO2-induced temperature rises.

These factors are discussed in text and diagrams

TAL IMPACT, THAW DEPTH, TESTS.

Traffic tests were conducted at two sites in northern Alaska with an air cushion vehicle, two light tracked vehicles, and three types of wheeled Rolligon vehicles

The traffic impact tsurface depression, effect on thaw depth, damage to vegetation, traffic signature visibility) was monitored for periods of up to 10 years

Data show the immidiate and long-term effects from the various types of vehicles for up to 50 traffic passes and the rates of recovery of the active layer. The air cushion vehicle produced the least impact. Multiple passes with the Rolligons caused longer-lasting damage than the light tracked vehicles because of their higher ground contact pressure and wider area of disturbance. Recovery occurs even if the initial depression of the tundra surface by a track or a wheel is quite deep (15 cm), as long as the organic mat is not sheared or destroyed.

TEMPERATURE EFFECTS, SHEAR STRESS.
In the growing field of ice engineering there is a need to establish standardized model tests of structures for use in environments. This study was designed to investigate the relative influence of vanous parameters on the kinetic friction coefficient between ice and different surfaces and determine which of those variables would need future, indepth investigation. Friction tests were performed with urea-doped, columnar ice, and the parameters of normal pressure, velocity, type of material, material roughness, ice hardness and test configuration were studied. Tests were conducted by pulling a loaded sample of ice over a sheet of material and by pulling a loaded sample of material over an ice sheet. An ambient temperature of -1.5C was maintained throughout the testing process, and the ice surface hardness was measured using a specially designed apparatus. The experimental results of the friction tests revealed that the behavior of the friction coefficient with varying velocity was significantly influenced by the test configuration and material roughness. Its magnitude was also affected by varying normal pressure, ice hardness, surface roughness and type of material

MP 1826 FLEXURAL STRENGTHS OF FRESHWATER MODEL ICE

Gow, A.J., IAHR International Symposium on Ice, 7th, Hamburg, F.R.G., Aug. 27-31, 1984. Proceedings, Vol.1, (1984), p.73-82, 4 refs.

ICE STRENGTH, FLEXURAL STRENGTH, LAKE ICE, ICE CRYSTAL STRUCTURE, ICE TEMPERATURE, GRAIN SIZE, TESTS.

TEMPERATURE, GRAIN SIZE, TESTS.
In this paper we present results of small beam tests performed on simulated lake ice corresponding in structure to the two major ice types, S1 and S2, encountered in lake ice covers. In these tests a combination of cantilever and simply supported beams was used to ascertain the dependence of flexural strength of the ice on its structure and temperature. It was found that macrocrystalline (S1) ice and columnar (S2) ice exhibit significant differences in bending strength and that substantial stress concentrations exist at the fixed corners of cantilever beams. Differences in response of S1 and S2 ice to bending forces clearly reflect variations in grain size, crystal orientation, temperature, and temperature gradient in the simulated ice, and these factors must be carefully considered when interpreting results of tests of the flexural strength of natural ice covers

MP 1827 ICEBREAKING BY GAS BLASTING. Mellor, M., IAHR International Symposium on Ice, 7th, Hamburg, F.R.G., Aug. 27-31, 1984. Proceed-ings, Vol.1, [1984], p 93-102, 6 refs

ICE BLASTING, ICE BREAKING, HIGH PRES-SURE TESTS, ICE COVER THICKNESS, GASES, TESTS, ICE LOADS, HYDRAULIC STRUC-TURES, EQUIPMENT.

TURES, EQUIPMENT.

Icebreaking texts utilizing high pressure air and CO(2), low pressure air, and fuel/oxidant combustion are reviewed and the results are interpreted. Applying cube root energy scaling to text discharges of approximately 1 MJ, it appears that fracture craters up to about 5.8 m/MJ(1/3) in diameter can be formed by optimum underwater blasts. Practical systems for clearing or displacing ice could be based on air guns developed for offshore seismic work, with gun pressure in the range 17-20 MPa and single-gun energy up to about 11 MJ. A procedure for making preliminary design calculations and safety appraisals is outlined, and it is concluded that a working "Super-Bubbler" need not be very complex or expensive.

QUIET FREEZING OF LAKES AND THE CON-CEPT OF ORIENTATION TEXTURES IN LAKE

Gow, A.J., IAHR International Symposium on Ice, 7th, Hamburg, F.R.G., Aug. 27-31, 1984. Proceedings, Vol.1, [1984], p.137-149, 6 refs. 39.1763

LAKE ICE, ICE CRYSTAL STRUCTURE, ICE NU-CLEI, FREEZING, TURBULENCE, TESTS.

CLEI, FREEZING, TURBULENCE, TESTS.
Several years' observations of the crystalline structure of ice sheets forming on a number of New England lakes indicate that just two major types of congelation ice are formed during quiet (non-turbulent) freezing of lake water These are. (1) ice sheets characterized by the growth of massive prismatic crystals exhibiting vertical or near-vertical c-axes probably equivalent to so-called S1 ice and (2) ice sheets composed predominantly of vertically elongated crystals exhibiting horizontally oriented c-axes, so-called columnar ice or S2 ice in this context of quiet freezing of lakes it was also determined that columnar textures are always associated with horizontal c-axis orientations of the crystals, whereas the development of c-axis vertical orientation is invariably linked with the growth of massive crystals. These observations have fostered the concept of orientation textures.

DYNAMICS OF FRAZIL ICE FORMATION. Daly, S.F., et al, IAHR International Symposium on Ice, 7th, Hamburg, F.R.G, Aug. 27-31, 1984. Proceedings, Vol.1, 1984, p.161-172, 10 refs. Stolzenbach, K.D.

FRAZIL ICE, ICE CRYSTAL GROWTH, HEAT TRANSFER, MATHEMATICAL MODELS, MASS TRANSFER, SURFACE PROPERTIES, ICE CRYS-TAL NUCLEL

This paper applies quantitative approaches of large-scale industrial crystallization to the study of frazil ice. The development of a crystal number continuity equation and a heat conservation equation can serve as a basis for predicting size distribution and concentration of frazil crystals. The size distribution and concentration of razil crystals in the key parameters in these equations are the crystal growth rate and the rate of secondary nucleation. The crystal growth rate is determined by the heat transfer rate from the crystals to the fluid, the intrinsic kinetics of the crystals. the crystals to the fluid, the intinuic kinetics of the crystals, surface tension, and the mass transfer rates. Available data indicate that the growth of the major axis of frazil crystals is controlled largely by heat transfer. The heat transfer expression for disks suspended in turbulent flow is presented. The rate of secondary nucleation can be expressed as the product of three functions, which relate the energy transferred to crystals by collision and the number of surviving crystals produced by the collision. The secondary nucleation rate is found to be a function of the turbulent energy dissipation and a strongly nonlinear function of the form and magnitude of the crystal size distribution. The number continuity and heat conservation equations are troublesome to solve simultaneously because they are nonlinear and dimensionally incompatible. However, the equations can be used in the development of models of frazil ice formation.

FIELD INVESTIGATION OF ST. LAWRENCE RIVER HANGING ICE DAMS.

Shen, H.T., et al, IAHR International Symposium on Ice, 7th, Hamburg, F.R. G., Aug. 27-31, 1984. Proceedings, Vol.1, [1984], p 241-249, 12 refs. Van DeValk, W.A.

ICE NAVIGATION, ICE CONTROL, RIVER ICE. PORTS, WINTER MAINTENANCE, ICE BREAK-ING, THERMAL EFFECTS, ICE REMOVAL, ICE

Successful methods of controlling ice in rivers and harb where winter navigation is maintained are described. These methods are developed from field and laboratory research studies and from operating experiences. The control of ice is achieved through layout and design of harbor facilities, management of traffic operations, and by using chemical, electrical, mechanical, and thermal methods including ice breaking, channel and flow modifications, air bubbling, warm

water discharges, resistance heating, coatings, and control structures. The control methods used must be evaluated in terms of reliability, safety, energy consumption, and environmental impact for costs and effectiveness for both docks and harbors. Thermal methods and mechanical methods most favored by these criteria.

ICE CONTROL, STRUCTURES, ICE SHEETS, ICE
BOOMS, ICE FORMATION, ICE COVER, COUNTERMEASURES, WATER FLOW.
Ice sheets are formed and retained in several ways in nature, and an understanding of these factors is needed before most ice sheet retention structures can be successfully applied. Many retention structures float and are somewhat flexible, others are fixed and rigid or semiring An example of the former is the Lake Erie boom and of the latter, the Montreal ice control structure lee sheet retention technology is changing. The use of timber cribs is gradually but not totally giving way to sheet steel pilings and concrete, but with caution. Ice-hydraulic analyses are helpful in predicting the effects of structures and channel modifications on ice cover formation and retention. Often, varying the flow rate in a particular system at the proper time will make the difference between whether a structure will or will not retain ice. The structure, however, invariably adds reliability to the sheet ice retention process.

MP 1833 ANALYSIS OF RAPIDLY VARYING FLOW IN

ICE-COVERED RIVERS.
Ferrick, M.G., IAHR International Symposium on Ice, 7th, Hamburg, F.R.G., Aug. 27-31, 1984. Proceedings, Vol.1, [1984], p.359-368, 6 refs.

RIVER FLOW, RIVER ICE, ICE COVER EFFECT, ICE BREAKUP, WATER WAVES, FRICTION, EXPERIMENTATION, ICE JAMS, ICEBOUND RIV-

ERS.
Rapidly varying flow waves are a primary cause of ice cover breakup on rivers.

Due to the presence of ice and the difficulties involved in determining conditions in the field, analyses of river waves during breakup are subject to much uncertainty. We conducted laboratory experiments to determine the effects of the ice cover upon these waves, and to identify the physical processes that produce these effects. The dimensionless friction scaling parameter of the St. Venant equations provides a quantitative estimate of the friction/inerita balance that dictates river wave behavior Knowledge of this balance is essential to interpretation and analysis of flow wave data. In this paper we apply the friction parameter in our interpretation of the laboratory data and address discrepancies between data and previous analyses of an ice jam release on the Athabasca River.

ICE CRYSTAL STRUCTURE, UREA, ARTIFI-CIAL ICE, MICROSTRUCTURE, ICE MODELS, SEA ICE, ICE STRENGTH, ICE SHEETS, TESTS. SEA ICE, ICE STRENGTH, ICE SHEETS, TESTS. Standard petrographic techniques were used for studying microstructure in thin sections of urea ice sheets now being used extensively in the CRREL. Test Basin for modeling sea ice. Depending mainly on the section in the column of urea-doped water two kinds of ice with radically different structural and mechanical properties have been identified in the one exhibiting vertical c-axis structure minimal urea is incorporated into the ice crystals, and ice sheets with this kind of structure tend to remain strong even after the temperature of the ice is raised close to its melting point. Ice of the second type is characterized by a preponderance of crystals exhibiting horizontal c-axes. This kind of ice, which is only produced when the test basin is seeded prior to freezing, also contains abundant inclusions of urea prior to freezing, also contains abundant inclusions of urea systematically incorporated into the crystals; the overall colum-nar structure of this ice closely resembles that of ordinary sea ice and optimum test conditions for modeling purposes are usually obtained with warm isothermal ice sheets of

EVALUATION OF A BIAXIAL ICE STRESS SENSOR.

Cox, G.F.N., IAHR International Symposium on Ice, 7th, Hamburg, F.R.G., Aug. 27-31, 1984. Proceedings, Vol.2. (1984), p.349-361.

PRESSURE RIDGES, ICE STRENGTH, COM-PRESSIVE PROPERTIES, STRAINS, TEMPERA-TURE EFFECTS, POROSITY, TESTS.

Over two hundred unconfined compression tests were performed on vertical ice samples obtained from 10 multi-year pressure ridges in the Beaufort Sea. The tests were performed on a closed-loop electrohydraulic testing machine at two strain rates 1/100,000 and 1/1,000/s and two tempera-tures (-20 and -5C). This paper summarizes the sample preparation and testing techniques used in the investigation and presents data on the compressive strength and initial tangent modulus of the ice.

EFFECTS, POROSITY, TESTS.

A series of 222 uniaxial constant-strain-rate compression tests was performed on vertical multi-year pressure ridge sea ice samples. A preliminary analysis of the effect of structure on the compressive strength of the ice was performed on 78 of these tests. Test parameters included a temperature of -5C (23F) and strain rates of 1/100,000 and 1/1,000/s. Columnar ice loaded parallel to the elongated crystal axes and perpendicular to the crystal c-axis was consistently the strongest type of ice. The strength of the columnar samples decreased significantly as the orientation of the elongated crystals approached the plane of maximum shear. Samples containing granular rice or a mixture of granular and columnar ice resulted in intermediate and low strength values. No clear relationship could be established between structure and strength for these ice types. strength values No clear relationship could be established between structure and strength for these ice types However in general, their strength decreased with an increase in porosity However.

CONSTRUCTION.

To date, the water-retaining structures constructed and maintained on permafrost in North America have been designed and built using a combination of soil mechanics principles for unfforce soils and unproven permafrost theory. In the USSR, at least five sizeable hydroelectric and water supply embankment dams as well as several small water supply embankment dams have been constructed and maintained on permafrost. The larger dams are understood to have performed well, but the smaller dams have been a mix of successes and failures. Specific criteria are still.

lacking for design, operation, and post-construction monitoring of water-retaining embankments founded on permafrost. The purpose of this presentation is to review the current practice, point out how it is deficient, and note what major problems need attention.

39-293 SOIL FREEZING, PHASE TRANSFORMA-TIONS, TEMPERATURE DISTRIBUTION, ANALYSIS (MATHEMATICS), FREEZE THAW CYCLES, UNFROZEN WATER CONTENT. THERMAL CONDUCTIVITY. PHASE TRANSFORMA-ATURE DISTRIBUTION.

THERMAL CONDUCTIVITY.

While many materials undergo phase change at a fixed temperature, soil systems exhibit a definite zone of phase change. The variation of unfrozen water with temperature causes the soil to freeze or thaw over a finite temperature range. Exact and approximate solutions are given for conduction phase change of plane layers of soil with water contents that vary linearly, quadratically, and exponentially with temperature. The temperature and phase change depths are found to vary significantly from those of the constant temperature or Neumann problem.

FLOATING ICE, ICE SHEETS, ICE COVER THICKNESS, DYNAMIC LOADS, ICE DEFOR-MATION, VELOCITY, TESTS.

MATION, VELOCITY, TESTS.

To determine the characteristic length of a floating ice sheet, the deflection of the ice sheet must be measured in response to a known load Deflection measurements with a deflectometer require reference to a fixed datum. A simple deflection measuring technique is described here that is based on integration of the response of a sensitive slope transducer to a moving load at constant speed. This procedure does not require reference to a fixed datum, instead the gravitational field acts as the datum. The characteristic lengths obtained from the slope-integration method compare very favorably with those obtained from direct measurement of deflections.

Data are presented on the variation of ice structure, salinity, Sea. Two continuous multi-year pressure ridges from the Beaufort Sea. Two continuous multi-year pressure ridge cores are examined as well as ree sample data from numerous other pressure ridges. The results suggest that the large scale properties of multi-year pressure ridges are not isotropic, and that the use of amisotropic ridge models may result in lower design ridge ice loads.

GRAIN SIZE AND THE COMPRESSIVE STRENGTH OF ICE.

Cole, D.M., International Offshore Mechanics and Arctic Engineering Symposium, 4th, Dallas, Texas, Feb. 17-21, 1985. Proceedings, Vol.2, New York, American Society of Mechanical Engineers, 1985. p 220-226, 15 refs. 39-2416

ICE STRENGTH, COMPRESSIVE PROPERTIES, GRAIN SIZE, STRESS STRAIN DIAGRAMS.

This work presents the results of uniaxial compression tests on freshwater polycrystalline ice. Grain size of the test material ranged from 15 to 5 mm, strain rate ranged from 171,000,000 to 17100/s and the temperature was -5 C. The grain size effect emerged clearly as the strain rate increased to 17100,000/s and persisted to the highest applied strain rates. On average, the stated increase in grain size brought about a decrease in peak stress of approximately 31%. The occurrence of the grain size effect coincided with the onset of stuble cracking. The strength of the material increased to a maximum at a strain rate of 11,000 s, and then dropped somewhat as the strain rate increased further to 1100 s. Strain at peak stress generally tended to decrease with both increasing grain size and increasing strain rate. The results are discussed in terms of the deformational mechanisms which lead to the observed behavior. This work presents the results of uniaxial compression tests

ICE LOADS, STRESSES, MEASURING INSTRU-MENTS, LOADS (FORCES), DESIGN, TESTS.

MENTS, LOADS (FORCES), DESIGN, TESTS. An elongated, uniaxual brass ice stress sensor has been developed by the University of Alaska and used in several field experiments. Laboratory calibration tests have been conducted, in a 60 x 29 5 x 8 5 in (1524 x 750 x 216 mm) ice block into which the sensor was frozen, to determine the sensor is response characteristics. Test results indicate that the sensor acts as a stress concentration with a stress concentration factor of 2 4 and transverse sensitivity of 13 at stresses below 30 lbf/sq in (207 kPa). At stresses greater than 30 lbf/sq in the stress concentration factor increased and the sensor exhibited a time delay response to load. Differences of 22% were measured between the measured sensor stress immediately after a constant ice load was applied and the asymptotic stress limit. Interpretation of measured sensor stresses can be considered reliable at ambient ice stress levels below 30 lbf/sq in

MP 1860 CALIBRATING CYLINDRICAL HOT-FILM ANEMOMETER SENSORS.

Andreas, E.L., et al, June 1986, 3(2), p.283-298, Refs. p.298

Murphy, B. 40-4484

ANEMOMETERS.

We report the results of 82 separate calibrations of cylindrical, platinum hot-film anemometer sensors in air. The calibrations for each sensor involved a determination of its temperaplatinum notining alternometer sensors in air. In canona-tions for each sensor involved a determination of its tempera-ture-resistance characteristics, a study of its heat transfer in forced convection, and an investigation of its yaw response. The convective heat transfer relation that we derive predicts the Nusselt number of the sensor as a linear function of R exp. 0.40, where R is the Reynolds number based on sensor diameter (1<R<43) For the 53 micrometer diame-ter sensors that we used, this heat transfer relation applies to wind speeds typical of the atmospheric surface layer, I to 20 m/s. From the heat transfer relation we also devise a method for determining hor-film operating characteris-tics at temperatures other than the calibration temperature-flinize's relation is the best model for the yaw response of these sensors, being valid over virtually the entire range of yaw angles, 0 to 90 deg. Although the yaw parameter is so weak in the atmospheric surface layer that k can be assumed constant at 0.3.

MP 1861 TECHNIQUE FOR OBSERVING FREEZING FRONTS

Colbeck, S.C., Jan. 1985, 139(1), p.13-20, 8 refs.

ICE WATER INTERFACE, FREEZING, ICE FOR-MATION. SOIL FREEZING, ICE LENSES,

On the basis of observations of freezing fronts and liquid inclusions in liquid-saturated glass beads, a simple technique is described for making these direct observations. The ice-water interface at the freezing front was concave when viewed from the ice side, because the glass beads were preferentially wetted by the liquid. The size and number of liquid inclusions decreased with distance behind the freezing front. of liquid inclusions decreased with distance behind the freezing front. More liquid is trapped by smaller glass beads. The liquid inclusions are probably enriched in soluble impurities. No tendency for pressure buildup or ice lense formation was observed, perhaps because large particles were used it is very important to extend these observations to other conditions, especially to smaller particle sizes.

FECTS, MATHEMATICAL MODELS.

Thermal measurements of the normal emittance of several diathermanous maternals were made at 152 C, 49 C and -5.6 C. Calculations of the total hemispherical emittance were made from normal emittance and plotted against the optical depth. A comparison of these data with a model proposed by Gardon indicates that at near-ambient temperatures they agree very closely. It has been observed that normal emittance is greater than hemispherical emittance by approx. 5% for both weakly and strongly absorbing maternals. This is attributable to phase differences in the multiply reflected internal radiation attempting to exit the specimen throughout steradians. Other radiation properties of the maternals, i.e. diffuse transmittance, absorption coefficient, and absorption index were calculated.

METEOROLOGICAL FACTORS.

Measurements are reported for attenuation and backscatter at 96, 140, and 225 GHz for falling snow and for mixed snow, sleet, and rain. The measurements were made with the Harry Diamond Laboratones Near-Millimeter Wave Mobile Measurement Facility at the SNOW-TWO Test at Grayling, MI, during the winter of 1983-1984. The dependence of the attenuation and backscatter levels on frequency, snow mass concentration, and ground-level air temperature are discussed. Measurements dade at 96 GHz with various combinations of transmitter and recover polarizations showed combinations of transmitter and receiver polarizations showed no polarization-related effects on the attenuation or backscatter

The requirement for improved quantification of obscuration parameters is generally recognized by those who attempt to measure, evaluate or predict electro-optical system performance during periods of adverse transmission conditions. A broad spectrum of measurement devices, ranging frem simple to extremely sophisticated, are presently in use for making obscurant measurements. To minimize duplication of effort and to help disseminate information on the current status of instrumentation, the Project Manager for Smoker/Obscurants tasked the U.S. Army Cold Regions Research and Engineering Laboratory with initiating a catalog of instrumentation current justed by government agencies and their contractors to make obscuration measurements.

SNOW CRYSTAL STRUCTURE, SNOWFALL, TRANSMISSION, ELECTROMAGNETIC PROP-ERTIES, SNOWFLAKES, ICE CRYSTAL REPII-CAS, ARTIFICIAL SNOW.

CAS, ARTIFICIAL SNOW.

Changes in snow crystal characteristics during snowstorms are frequently observed. A continuous record of these changes is required to study the effect of airborne snow on the transmission properties of electromagnetic energy. A continuous snow crystal replicator suitable for this task has been developed and was field-tested at the SNOW.

Il exercise. This replicator, which employs a Formvar technique for snow crystal replication developed by Schaefer (1956) possesses electronic and mechanical features previously unavailable in other replicators and represents a significant improvement in Formvar replication technique. A microprocessor controls the operation of the replicator, resulting in improved quality of snow crystal replicas as well as a decrease in data reduction time. This is accomplished by 1) regulating the temperature of a heater bar designed to reduce blushing (condensed moisture on the film which obscures the detailed structures of replicated crystals), 2) ensuring uniform thickness of the Formvar coating by adjusting the flow rate according to film speed, 3) encoding time on the film, and 4) monitoring moiston of the film to ensure proper operation of the replicator. A description of this instrument is presented and details of its operation at SNOW II are discussed. Il exercise. This replicator, which employs a Formvar Il are discussed

NEW METHOD FOR MEASURING THE SNOW-SURFACE TEMPERATURE

Andreas, E.L., Dec. 1984, SR 84-35, Snow Symposium, 4th, Hanover, NH, Aug. 14-16, 1984. Proceedings, Vol.1, p.161-169, ADB-090 935, 5 refs. 39.7959

39-2959 SNOW SURFACE TEMPERATURE, HUMIDITY, HYGROMETERS, DEW POINT, SURFACE ROUGHNESS, METEOROLOGICAL DATA, THERMISTORS, ANALYSIS (MATHEMATICS).

Because of the tenuousness of a snow cover, measuring its surface temperature is not easy. The surface is ill-defined and easily disturbed, invasive transducers commonly used for other surfaces may thus be inappropriate for snow A hygrometric method is described for measuring the snowand non-radiative and that it depends only weakly on the surface temperature, the advantages are that it is non-invasive and non-radiative and that it depends only weakly on the surface structure. The key assumption is that air at a snow surface is in saturation with the snow, the dew-point temperature of the air is thus T(s), the surface temperature Consequently, under the right conditions, by measuring the dew-point temperature 10 cm above the surface, we, in effect, measure the surface temperature

OVERVIEW OF METEOROLOGICAL AND SNOW COVER CHARACTERIZATION AT SNOW-TWO.

Bates, R.E., et al, Dec. 1984, SR 84-35, Snow Symposium, 4th, Hanover, NH, Aug. 14-16, 1984 Proceedings, Vol.1, p.171-191, ADB-090 935, 6 refs. O'Brien, H.W.

TURE DISTRIBUTION, GRAIN SIZE, TESTS.

The performance of military airborne down-look systems, regardless of wavelength, depends upon the recognition of differences between target and background features as viewed through an intervening medium. In cold regions the background may consist partially or entirely of snow cover during winter months. Prediction or evaluation of system performance under such conditions requires detailed characterization of snow cover, meteorological situation and, in some cases, subsurface features such as soil. This paper presents a brief overview of meteorological and snow cover background measurements made at Camp Grayling, Michigan, during SNOW-TWO. Eight independent system tests were supported, each of which required meteorological and/or snow-over "ground-truth" characterization. Support was provided at four meteorological sites and seven snow cover characterization locations. Methodology is described briefly and a listing given of available data taken by CRREL in support of these tests.

Koh, G., Dec. 1984, SR 84-35, Snow Symposium, 4th, Hanover, NH, Aug. 14-16, 1984 Proceedings, Vol 1, p.247-259, ADB-090 935, 9 refs 39-2965

SNOWFALL. TRANSMISSIVITY. ATTENUA-TION, SNOW CRYSTAL STRUCTURE, SOLAR RADIATION, PARTICLE SIZE DISTRIBUTION, ELECTROMAGNETIC PROPERTIES, MATH-EMATICAL MODELS, FALLING BODIES, IN-FRARED RADIATION, RADIATION ABSORP-

TION.

The attenuation of electromagnetic energy transmitted through failing snow can be determined if sufficient information regarding the physical and optical properties of airborne snow is known. Due to the complex and dynamic nature of falling snow the necessary parameters to predict transmission are often difficult to measure. Therefore it is necessary to carefully evaluate all the snow properties that are measurable in order to identify some ideal set of snow parameters that can be used to adequately model transmission through falling snow. A basic quantitative measurement of falling snow that can be continuously monitored is the mass concentration. Thus an approach to modeling transmistance through airborne snow using mass concentration as one of the inputs should be thoroughly investigated. This paper explores

a potential method of predicting transmittance based on mass concentration measurement, taking into consideration the size and shape of the snow crystals. Although the paper focuses on visible radiation the concepts discussed are also applicable to infrared radiation.

FORWARD-SCATTERING CORRECTED EX-TINCTION BY NONSPHERICAL PARTICLES. Bohren, C.F., et al, Dec. 1984, SR 84-35, Snow Symposium, 4th, Hanover, NH, Aug. 14-16. 1984. Proceedings, Vol.1, p.261-271, ADB-090 935, 16 refs. Koh, G. 39-2966

SNOW CRYSTAL STRUCTURE, LIGHT SCAT-TERING, SNOWFLAKES, WAVE PROPAGA-TION, PARTICLES, ANALYSIS (MATHEMAT-ICS).

Measured extinction of light by particles, especially those much larger than the wavelength of the light illuminating them, must be corrected for forward scattered light collected by the detector Near-forward scattering by arbitrary nonspherical particles is, according to Fraunhofer diffraction theory, more sharply peaked than that by spheres of equal projected area. The difference between scattering by a nonspherical particle and that by an equal-area sphere is greater the more diffusely the particle's projected area is distributed about its centroid. Snowflakes are an example of large atmospheric particles that are often highly nonspherical. Calculations of the forward-scattering correction to extinction by ice needles have been made under the assumption that they can be approximated as randomly oriented prolate spheroids (aspect ratio 10-1). The correction factor can be as much as 20% less than that for equal-area spheres depending on the detector's acceptance angle and the wavelength. Randomly oriented oblate spheroids scatter more nearly like equal-area spheres.

REMOTE SENSING, SNOW PHYSICS, ICE PHYSICS, REFLECTION, RADAR ECHOES, WAVE PROPAGATION, SNOW ACOUSTICS, ICE ACOUSTICS, ELECTROMAGNETIC PROPER-TIES.

A new approach was developed for computing the impulse response of a layered material. Our approach is different from other formulations in that we rely on a simple algorithm for polynomial division rather than the usual and more cumbersome matrix schemes. Our model is strictly valid for normally incident plane waves and does not allow for dispersion in a lossy material but we can account for geometrical spreading ano believe the technique can be adapted for oblique incidence. The advantages of our technique are simplicity and the impulse nature of the solution. Consequently, we can compute the band limited response of the layered material through a straightforward convolution of the impulse response with any desired source function. In this paper, we outline the method and discuss examples of radar waves reflected from layers of snow and ice. We suggest the method may be a convenient tool for modelers studying acoustic and electromagnetic reflections from snow and ice cover. for polynomial division rather than the usual and more co

JAMS, DAMS, ELECTRIC POWER, FLOODS, RAIN, MATHÉMATICAL MODELS.

RAIN, MATHEMATICAL MODELS.

In this paper we consider long-period, shallow-water waves in rivers that are a consequence of unsteady flow. River waves result from hydroelectric power generation or flow control at a dam, the breach of a dam, the formation or release of an ice jam, and rainfall-runoff processes. The Saint-Venant equations are generally used to describe river waves. This paper is an investigation into areas which are fundamental to river wave modeling. The analysis is based on the concept that river wave behavior is determined by the balance between friction and inertia. The Saint-Venant equations are combined to form a system equation that is written in dimensionless form. The dominant terms of the system equation change with the relative magnitudes of a group of dimensionless scaling parameters that quantify the friction-inertia balance. These scaling parameters are continuous, indicating that the various river wave types and the transitions between them form a spectrum

ICE STRENGTH, COMPRESSIVE PROPERTIES. STRESS, STRAIN DIAGRAMS, TESTS, MEASURING INSTRUMENTS

ING INSTRUMENTS
Procedures have been refined for performing constant-strain rate triangla tests on ice samples such that the confining pressure axial stress ratio femanic constant. Sample axial displacements are measured inside the cell on the sample and outside the cell between the cell and the loading priston. In addition to reviewing the development of the equipment and testing procedures, data are presented to illustrate the problems of using outside displacement measurements. In general, direct axial displacement measurements on the sample are essential to obtain accurate test strain rates and ice moduli. This is particularly true for brittle ice at low temperatures, high strain rates, and high confining pressures.

MP 1879 SHEAR STRENGTH IN THE ZONE OF FREEZ-ING IN SALINE SOILS.

Chamberlain, E.J., Conference Arctic '85. Proceedings Civil engineering in the Arctic offshore. Edited by F.L. Bennett and J.L. Machemehl, New York, American Society of Civil Engineers, 1985, p.566-574, 39-3205

FROZEN GROUND STRENGTH, SALINE SOILS, SHEAR STRENGTH, DEFORMATION, SOIL FREEZING, CLAY SOILS, SANDS, SEA WATER, TEMPERATURE EFFECTS, TESTS.

TEMPERATURE EFFECTS, TESTS.

Laboratory direct shear strength tests were conducted on sand and clay soil samples as they were freezing. Samples prepared with seawater and distilled water were tested in a modified direct shear box at shear plane temperatures ranging from 0 C to -5 C. The shear strengths of the freezing saline clay and sand samples were observed to be significantly less than shear strengths or the fresh water samples. For the clay samples, these shear strength differences could be accounted for principally by the 1.8 C freezing point depression caused by the salts in the sea water, the two shear strength curves nearly paralleling and overlapping each other when plotted versus temperature below freezing in a similar plot for the sands, the two curves diverge considerably from a common strength at 0 C. It is shown that the shear strength reduction of the saline clay soil is principally the result of increased unfrozen water content It is postulated that knowledge of unfrozen water content relationships for frozen saline soils will probably allow better predictive capabilities for the shear strength in the freezing zone.

There would be broad scientific benefit in establishing in Alaska an imaging radar receiving station that would collect data from the European Space Agency's Remote Sensing Satellite, ERS-1; this station would acquire imagery of the ice cover from the American territorial waters of the Beaufort, Chukchi, and Bering Seas, this station, in conjunction with similar stations proposed for Kiruna, Sweden, and Prince Albert, Canada, would provide synoptic coverage of nearly the entire Arctic The value of such coverage to aspects of occanography, geology, glaciology, and botany is considered.

CONTROLLING RIVER ICE TO ALLEVIATE ICE JAM FLOODING.

Deck, D.S., IAHR International Symposium on Ice, 7th, Hamburg, F.R.G., Aug. 27-31, 1984 Proceedings, Vol.3, [1984], p.69-76, 4 refs.

ICE CONTROL, RIVER ICE, ICE JAMS, FLOODS, ICE BOOMS, ICE BREAKUP, ICE COVER THICKNESS, MODELS, COUNTERMEASURES.

NESS, MODELS, COUNTERMEASURES.

Many communities affected by ice jam flooding have accepted the event as unpreventiable. Others have approached their problem as one of open channel flow and implemented standard projects such as channel modifications or dikes to combat their flooding. We feel that the best approach is to control the river ice before it poses a problem, by controlling either freeze-up or break-up. This paper addresses our involvement at two areas where ice jam flooding has caused severe economic hardship and loss of life. An ice boom has been used to control the formation of river ice at Oil City, Pennsylvania, and a permanent ice control structure will be constructed on Cazenovia Creek in West Senecs, New York, to control the river ice during break-up.

HEAT AND MOISTURE ADVECTION OVER ANTARCTIC SEA ICE. Andreas, E.L., May 1985, 113(5), p.736-746, 27 refs.

ICE EDGE, HEAT LOSS, SEA ICE DISTRIBUTION, PACK ICE, ANTARCTICA—WEDDELL SEA.

SEA.

Surface-level meteorological observations and upper-air soundings in the Weddell Sea provide the first in situ look at conditions over the deep antarctic ice pack in the spring. The surface-level temperature and humidity were relatively high, and both were positively correlated with the northerly component of the \$50 mb wind vector as far as 600 km from the ice edge. Since even at its maximum extent, at least 60% of the antarctic ice pack is within 600 km of the open ocean, long-range atmospheric transport of heat and mosture from the ocean must law a key part in antarctic. and mosture from the ocean must play a key part in antarctic sea ice heat and mass budgets. From one case study, the magnitude of the ocean's role is inferred at this time of year the total turbulent surface heat loss can be greater under southerly winds than under northerly ones. (Auth.)

ENERGY EXCHANGE OVER ANTARCTIC SEA ICE IN THE SPRING.

Makshtas, A.P.

SEA ICE, ABLATION, RADIATION BALANCE, HEAT FLUX.

In October and November of 1981, during the US-USSR Weddell Polynya Expedition, we made the first measurements ever of the turbulent and radiative fluxes over the interior pack ice of the southern ocean The daily averaged, surface-averaged sum of these fluxes—the so-called balance, which averaged sum of these fluxes—the so-called balance, which comprises the conductive, heat storage, and phase-change terms—was positive for all but one day during the cruise, the ablation season had begun. Of ariability in the sum of the turbulent fluxes produced most of the variability in the balance. These turbulent fluxes generally correlated with the geostrophic wind—a northerly wind (in off the ocean) transferring heat to the surface, and a southerly wind removing it. (Auth)

USE OF REMOTE SENSING FOR THE U.S. ARMY CORPS OF ENGINEERS DREDGING PROGRAM.

PROGRAM.

McKim, H.L., et al, International Symposium on Remote Sensing of Environment, 18th, Paris, France, Oct. 1-5, 1984. Proceedings, Ann Arbor, Environmental Research Institute of Michigan, (1985), p.1141-1150, Refs. p.1147-1149. Klemas, V., Gatto, L.W., Merry, C.J. 39-3707

REMOTE SENSING, DREDGING, SEDIMENT TRANSPORT, CHANNELS (WATERWAYS), SUSPENDED SEDIMENTS, ENVIRONMENTAL

IMPACT.

The objectives of this study were to review the uses of existing remote sensing techniques for providing data in the Corps of Engineers dredging program, to define promising new techniques for monitoring dredging operations, and to recommend those techniques that should be used now and those to be developed for future use. The uses for which remote sensing techniques were evaluated include channel surveys and engineering considerations, monitoring of sediment drift and dispersion during dredging operations, monitoring of water quality and suspended sediment concentration, disposal site selection and monitoring of environmental effects at disposal sites, and long-range dredged material disposal management strategies

MP 1891 FULL-CYCLE HEATING AND COOLING PROBE METHOD FOR MEASURING THER-MAL CONDUCTIVITY.

McGaw, R., (1984), No.84-WA/HT-109, 8p. 32

39.3902 THERMAL CONDUCTIVITY, COOLING, HEAT-ING, THERMAL DIFFUSION, ANALYSIS (MATHEMATICS), TESTS.

(MATHEMATICS), tESTS.

A modification of the traditional probe test procedure is described which incorporates the cooling stage that succeeds each heating stage. The improved procedure enables ascond value of thermal conductivity to be determined for each test. A comparison between the two values gives a measure of the experimental error for the test, and provides a means by which physical changes within the test specimen may be detected. If the ambient test temperature of the specimen has thered during a test, the effect on the test values may also be determined through a comparison of the heating-stage and cooling-stage temperatures

The test imposes two freeze-thaw cycles on four soil samples. The data logger is set up with 3-10 channel multiplexer cards for analog measureset up with 3-10 channel multiplexer cards for analog measurement and actuator control. Two of the multiplexer cards are configured for a total of 36 single-ended thermocouple measurements which are accurate to plus or minus 0.1 C. The third multiplexer card is configured with two actuator switches to control the temperatures of two refrigerated circulating baths and with five double-ended channels to read the output of four linear motion DC transformers and one power supply

The data acquisition/control unit is controlled using a HP41CX hand-held calculator and the HP41CX hand-held calculator and the HP41CX hand-held calculator and the HP41CX thand-held calculator and the HP41CX thand-held calculator is programmed with over 30 programs and subroutines to control the temperature, and to reduce, print out, store and plot the test data

A new method is presented for solving two-dimensional axisymmetric heat conduction problems with phase change. axisymmetric heat conduction problems with phase change. A strict discontinuity between phases is assumed, and no artificially smoothed enthalpy transition between phases need be introduced. Step changes across phase boundaries in the sensible heat capacity and thermal conductivity are accommodated, when the phase change isotherm cuts arbitrarily across a fixed mesh of linear triangular finite elements. Latent heat effects are accounted for through a Dirac delta function in the heat capacity.

This is absorbed mathematically and the effects described and the effects are accounted for through a Dirac delta function in the heat capacity. tent near effects are accounted for integer a price tentile function in the heat capacity. This is absorbed mathematically and its effects distributed appropriately over discrete mesh entities in the course of ordinary Galerkin finite element procedures. Computed results agree well with analytical solutions in the limited cases where they are available, and numerical results in more general cases behave quite reasonability.

FROST HEAVE, UNFROZEN WATER CONTENT, SOIL WATER, SUPERCOOLING, PRESURE, PHASE TRANSFORMATIONS, SOIL FREEZING, ANALYSIS (MATHEMATICS).

The role of the phase equil-brim of water in frost heave was studied for two kinds of soil. The rate of frost heave and the rate of water intake were measured simultaneously under various rates of heat removal. The experimental data revealed a trend common for both soils that the rate of materials and the rate of the soils that the rate of materials are revealed as trend common for both soils that the rate data revealed a trend common for both soils that the rate of water intake attains its maximum at a certain critical rate of heat removal. The data were analyzed by using equations accurately describing the relation between these rates. The results of the analysis indicate a senious doubt about the validity of phase equilibrium in the system. Alternatively, an assumption was introduced that supercooling occurred between a frost front and an unfrozen part of the soil. It was shown that supercooling could explain the data well under certain conditions.

TESTS.

The amount of water migration in an unsaturated frozen soil, morin clay, was determined in horizontally closed soil columns under linear temperature gradients. The temperature at the warm end of the soil column was below its freezing point at the initial water content in order to keep the soil specimen always in the frozen state during testing. The flux of water migration was calculated from the distribution curves of the total water content before and after testing. Four factors affecting the flux, including temperature, temperature gradient, test duration and the dry density of the soil, were investigated. It was found that the flux is directly proportional to the square root of the test duration, decreases with the decrease in temperature in the power law form, and changes with the dry density. The behavior of water migration in unsaturated, frozen morin clay is something like that in the unsaturated, unfrozen soils.

STRAIN RATE EFFECT ON THE TENSILE STRENGTH OF FROZEN SILT.

VOLUME), TESTS.

Tension tests at constant rates were conducted on remolded saturated frozen Fairbanks silt with medium density at 5 C for various machine speeds. It is found that the ensite strength depends strongly upon strain rate and the critical strain rate for ductile-brittle transition was about 1/100s. The peak tensile strength considerably decreases with decreasing strain rate for ductile failure, while it slightly decreases with increasing strain rate in the brittle region. The failure strain also varies with strain rate, but the initial tangent modulus is found not to be dependent upon strain rate.

ICE SHEETS. STRESSES. ICE LOADS. OFF-SHORE STRUCTURES, ICE CONDITIONS, ICE PRESSURE, THERMAL EXPANSION

Cylindrical biasial stress sensors were used to measure ice stress variations as a function of depth across an ice peninsula

on the shoreward side (south) of Kadluk Island. The stresses varied in a complex manner both laterally and with depth in the ice sheet. Average stresses were calculated and summed across the ice peninsula to determine the ice load acting on the structure. The maximum measured average stress and corresponding calculated structural load during the experiment were about 300 kPa and 150 MN respectively. All significant measured stresses were caused by thermal expansion of the ice sheet.

TEMPERATURE, STATISTICAL ANALYSIS.

A small ice island fragment was found in a unique location southwest of Cross Island, Alaska, in April 1983 Investigations were made to determine the thickness, salinity, density, internal temperature, and strength of the ice island ice Measurements were also made which revealed that the ice island was grounded. Side scan sonar, depth profiles and direct sounding measurements of the sea bottom revealed that the ice island had gouged into the seabed when it was driven into shallower waters. Implications of this ice feature to offshore petroleum development are discussed

MP 1901 APPARENT UNCONFINED COMPRESSIVE STRENGTH OF MULTI-YEAR SEA ICE.

Kovacs, A., International Conference on Port and Ocean Engineering under Arctic Conditions, 8th, Narssarssuaq, Greenland, Sep. 7-14, 1985. Proceed-ings, Vol.1, Hörsholm, Denmark, Danish Hydraulic Institute, 1985, p.116-127, 4 refs.

ICE DENSITY, BRINES, TESTS.

An axial double-ball load test system for determining the apparent unconfined compressive strength of multi-year sea ice was evaluated. The effects of loading ball size, ice temperature, and brine free density on the apparent unconfined compressive strength of the ice were investigated. Axial double-ball load test results are compared with those obtained from labor intensive conventional unconfined compression tests made on similar density ice. The results from the two testing methods were found to agree very well, indicating that the axial double-ball load test may be used to provide a rapid method for determining an apparent unconfined compressive strength index for ice.

INVESTIGATION OF THE ELECTROMAGNET-IC PROPERTIES OF MULTI-YEAR SEA ICE.

ECHOES.

Sounding of multi-year sea ice, using impulse radar operating in the 80- to 500-MHz frequency band, revealed that the bottom of this ice could not always be detected. This paper discusses the results of a field program aimed at inding out why the bottom of thick multi-year sea ice could not be profiled and at determining the electromagnetic (EM) properties of multi-year sea ice. It was found that the bottom of the ice could not be detected when the ice structure had a high brine content. Because of brine's high conductivity, its volume dominates the loss mechanism in first-year sea ice, and the same was found true for multi-year sea ice. A two-phase dielectite mixing formula, used by the authors for describing the EM properties of first-year sea ice, was modified to include the effects of the gas pockets found in the multi-year sea ice. This three-phase mixture model was found to estimate the EM properties of the multi-year ice studied over the frequency band of interest. The latter values were determined by 11 vertical sounding to a subsurface target of known depth and 21 cross-borchole transmission measurements

DEPTH, GREENLAND SEA.

DEPTH, GREENLAND SEA.

The physical properties of sea ice in the Fram Strait region of the Greenland Sea were examined during June and July 1984 in conjunction with the MIZEX field program. The properties of the pack ice in the Fram Strait are believed to be representative of ice from many locations within the Arctic Basin since Fram Strait is the major ice outflow region for the Basin Most of the ice observed and sampled was multi-year. The majority of the first-year ice appeared to have been deformed prior to entering Fram Strait. The properties measured at each sampling site included salinity, temperature, thickness, crystal structure and snow depth. The measured salinities agreed well with those taken during summer at other locations in the Arctic. An important finding was that snow depths on multi-year ice were much larger than those on first-year ice. Finally, the crystal structure analysis indicated that about 75% of the ice consisted of congelation ice with typically columnar type crystal structure. The remaining 25% consisted of granular ice

A simulation model for sea rec-induced gouges on the shelf of the Beaufort Sea is developed by assuming that annual occurrence of new gouges is given by a Poisson distribution, locations of the gouges are random, and distribution of gouge depths is specified by an exponential distribution. Once a gouge is formed it is subject to infilling by transport of sediment into the region and by local movement of sediment along the sea floor These processes are modeled by assuming a sediment input based on stratigraphic considerations and by calculating bedload transport using methods from sediment transport theory. It is found that if currents are sufficient to transport sediment, rapid infilling of gouges occurs.

Small-scale experiments were performed to determine sheet ice forces on a control structure. The experiments were conducted with a 45 deg upward breaking conical structure which had diameters of 15 m at the waterline and 0.33

m at the top. The surface of the structure was initially smooth; later it was roughened to investigate the effect of surface friction on the ice load. The thickness and the flexural strength of ice sheets were varied, and the tests were conducted at three fixed velocities.
